

Houston Botanic Garden Land Care Institute

Mission:

To inspire and educate land care professionals to design and maintain systems that promote and sustain healthy ecosystems.

We are thrilled to present to you Houston Botanic Garden's Land Care institute.

The first of its kind in our city, our program changes the goal of landscaping from purely aesthetic, to functional and holistic benefiting people and the planet. The management of the landscape occurs before, during, and after installation in a manner that promotes and sustains the immediate and surrounding environment.

The land that surrounds us, our homes, whether it is a side, front, or back yard is directly tied to our health and well-being. There is so much potential to bring back landscapes that resemble and mimic nature, which is shown to have numerous physical and psychological benefits. Our goal is to avoid the current landscaping industry trend to primarily promote a mechanical/chemical approach, encouraging pesticide/herbicide/fungicide use, causing harm.

Our goal in bringing this program to Houston is to educate, empower, and guide landscapers and homeowners towards a different way of interacting with their land in a way that values life and connects us all. By learning about our regional native plants, soil biology, ways to mitigate and manage rainwater and erosion, participants not only will design beautiful landscapes, but will also support landscape function. They will learn to create balanced and well-designed systems that reduce waste, save costs, mitigate challenges, and connect us to nature.

Houston Botanic Garden's Landcare Institute is a hybrid certification program lasting over forty hours of detailed education and advice. Participants will have the opportunity to be featured on our website and in a directory of certified individuals and institutions. We will host these training courses twice a year and begin to host gatherings and round tables twice a year.

Below you will find the key principles that will serve as the foundation for this program.

Key Principles:

Here are a few sustainable landscape ideas that adhere to green infrastructure's core tenets and boost the benefits you can reap by implementing them.

1. Conserve Water

One of the biggest benefits of regenerative landscape design is that it helps save water.

Using native plants for borders and foundations can cut down on the amount of supplemental water one needs to keep those plants growing strong. These plants are naturally adapted by region and have evolved to be more tolerant to the weather patterns and soil conditions, which means they may require less supplemental watering

than introduced species. To maximize the use of exterior commercial spaces, especially throughout the year, one is able to take advantage of Mother Nature's best features.

Controlling runoff and stormwater is another way to treat water as a resource. Using permeable surfaces like gravel walkways – rather than concrete or asphalt – allows rainwater to soak into the soil, rather than flow into storm drains without benefiting the landscape.

2. Use Native Plants to Reduce Pesticides

It is possible to reduce commercial landscape maintenance costs by using native plants with a sustainable landscape design.

For example, using plants like Wild Geraniums, Purple Coneflower, and Black-eyed Susan where they are native [can reduce fertilization and pesticide use](#) on commercial properties. These plants don't require supplemental inputs because they can withstand the varied weather conditions and pests in the region. There are many more examples of native plants that can be used to create beauty without the extra maintenance of many popular ornamental flowers.

Note: Don't be alarmed if you see some holes chewed in the leaves of your native plants. It just means that your ecosystem is thriving!

3. Use Trees to Provide Shade for Buildings and Reduce Energy Costs

Another way you can make commercial sites more eco-friendly is by planting deciduous trees on the southern and western sides of buildings to block the sun's rays during the hottest parts of summer days. This reduces the building's cooling needs from air conditioning – in fact, it's not uncommon to see up to 50% savings.

During the winter, those trees lose their leaves and enable sun to warm the building, reducing heating bills. To find out how much the trees on a property can save – or to estimate the benefits of new trees, check out [i-Tree](#) from the USDA Forest Service.

4. Use Ground Cover Plants to Reduce Erosion

Some conditions like rain, wind, foot traffic and overuse can promote soil erosion on commercial properties. Planting ground cover plants can protect the soil, preventing these areas from wearing away. Additionally, plants with deep roots help stabilize soil particles, and plants' leaves take the impact of falling rain and help reduce erosion. If there is an area that is not designated as a green space, mulching is a great alternative to groundcovers as it prevents erosion, creates great pathways, and establishes an ecosystem for bacteria and fungi to thrive, which helps to build soil and boost plants!

5. Maximize Greenspace Throughout All Seasons

Use simple environmentally friendly landscape design techniques to [create microclimates on your commercial property](#).

This enables longer enjoyment of various areas of commercial properties. How does this work? Small temperature changes can be manipulated warmer by using slope, wind, orientation, walls/fences, seating, and plant material choices to one's advantage, giving gardens a chance to be enjoyed longer – even as the seasons begin to shift.

Costs can be reduced by creating low-maintenance spaces using native wildflowers or mulch on commercial sites – possibly where there is little traffic or use – that require very little mowing, reducing emissions and fuel expenses.

6. Observe and Interact

Before starting to design any project, make sure time is taken to observe before interacting. Sites should be observed before meeting with a client.

Observe what happens during heavy rainfall, summer drought, learn where the sun is the strongest and watch for any problem areas relating to infrastructure or water flow. If there is a deadline and no time to observe, use the resources available (local folks, landlord, owner of property) to help to understand how the different elements of nature move about the property. This will help to create a smart design that will avoid costly changes down the line.

7. Catch and Store Energy

When nature provides abundance, it is the designer's role as part of nature to utilize and respectfully catch the energy that is bountiful and available. What are forms of energy? Sun, Rain, Wind, Plant material can be captured now to have it for later when it is needed. Designing systems so that the energy is captured and stored is the essence of resilience within the landscape.

8. Use and Value Renewable Resources

Nature is providing abundance, and it falls on designers and installers to maximize it by reducing waste and considering resources. Diverse sources of lumber, stone, pavers, soil and mulch, both new and used, can turn waste into value. Consistently search for and connect with reused and reusable resources.

9. Use and Value Diversity

Increasing biodiversity is one of the ways to keep your garden pest and disease free. Allowing IPM (Integrated Pest Management) To lead the pest control issue through increasing habitat for predatory insects to thrive, providing them food via pests that are hurting your plants.

Examples and Components of Sustainable Landscaping

There are quite a few tools used in regenerative building practices that apply to the field of landscaping and help meet some of these key sustainable landscape principles.

Quite a few of these design tools can help one better manage stormwater at a site.

A rain garden, for instance, features deep-rooted native plants that collect and allow stormwater to soak slowly into the ground, rather than simply rush into the nearest storm drain. Rain gardens filter pollutants from the water as it flows through its abundant plant life.

Healthy drainage systems to [direct stormwater to preferred channels](#) ensure rainwater enters bioretention basins. Think of this as a more advanced rain garden that includes drainage systems.

Water naturally runs more quickly along concrete pathways. Using surfaces like gravel or permeable pavers helps reduce this rapid water flow and allows for more natural filtration throughout the landscape.

In areas of the country that lack water, using drought-tolerant and water-conserving plants in a xeriscape design can also reduce maintenance and costs while keeping commercial sites looking well-maintained.

*We are partnering with and abiding by NOFA standards of Organic Agriculture for natural landscapes Below you will find the key principles that we are using as the basis for this program – The NOFA Standards for Organic Land Care. NOFA's mission is to extend the vision and principles of organic agriculture to the care of landscapes that surround us in daily lives. We hope these standards can provide guidance and support when thinking about design and implementation of future projects

*This program is made possible by mentorship and the generosity of Phipps's Conservatory and Botanical Garden in Pittsburgh, Pennsylvania.

THE NOFA ORGANIC LAND CARE PROGRAM

Mission Statement

The Mission of the NOFA Organic Land Care Program is to extend the vision and principles of organic agriculture to the care of the landscapes that surround us in our daily lives.

Definition of Organic Land Care

Organic Land Care is a sustainable ecological landscaping system that promotes and enhances biodiversity, biological cycles, and soil biological activity. It is based on minimal use of off-site inputs and on management practices that restore, maintain, and enhance ecological harmony and beauty in urban and suburban landscapes and gardens. “Organic” means landscaping with no synthetic pesticides of any kind (insecticides, herbicides, fungicides, etc.) and with no synthetic fertilizers or soil amendments.

Basic Principles of Organic Land Care

Adapted from the “Principles of Organic Agriculture,” International Federation of Organic Agriculture Movements [IFOAM]

1. **Principle of Health.** Organic land care should sustain and enhance the health of soil, water, air, plant, animal, human, and planet as one and indivisible.
2. **Principle of Ecology.** Organic land care should be based on ecological systems and cycles and should work with them, emulate them, and help sustain them.
3. **Principle of Care.** Organic land care should be managed in a precautionary and responsible manner to protect the health and well-being of current and future generations and the environment.
4. **Principle of Fairness.** Organic land care should build on relationships that ensure fairness with regard to the common environment and life opportunities. Fairness is characterized by equity, respect, justice, and stewardship of the shared world, both among people and in their relationships to other living beings.

These principles are closely interrelated.

Health is the maintenance of human, physical, and mental wellness, and social and ecological well-being.

Organic land care fosters healthy ecosystems, which include the smallest soil microorganisms, plants, and animals, including human beings. The sustained health of the planet depends on ecological diversity, resilience, and sustainability of ecosystems.

Organic land care practitioners strive to avoid pollution in establishing and caring for landscapes.

Ecology is the study of relationships among living things in a community. Organic land care uses ecological principles to sustain the health of plants and soils. Practices that enhance communities of living organisms and biological cycles are site specific.

In nature, ecosystems sustain themselves with no intervention. We try to mimic these systems in our managed landscapes. When inputs are needed, e.g., soil amendments, renewable materials from local sources are preferred.

Organically managed landscapes are designed to protect the diversity of the land and its surroundings, such as native plants and wildlife habitats.

“Right plant, right place,” a key tenet of the Organic Land Care Program, refers to choosing plants for the environment, not altering the environment to fit a plant choice. Plants have evolved to grow in certain landscape niches and using this knowledge will allow the creation of resilient, low-input landscapes.

Plants that are selected, planted, and grown according to these principles thrive over long periods and better tolerate normal climatic cycles.

Care is the consideration of social and ecological impacts of the materials and techniques used in landscape creation and management.

“Do no harm” refers to land use decisions that have positive or neutral effects on the land. Organic land care protects and enhances the natural elements on a site. Before changes are made, a thorough site assessment must be conducted to discover the natural elements and how they interact with each other. If the assessment shows the site to be damaged or lacking in certain elements,

restoration or remediation becomes part of the landscape plan. Studying existing nearby natural areas is the best way of approaching site restoration.

Fairness implies stewardship of the earth and all its creatures. An organic land care employer demonstrates strong ethical practices, including fair distribution of assets and benefits. Our businesses respect nature, family needs, and personal values. Also, business goals must be sustainable, i.e. economically sound, socially acceptable, and environmentally benign.

Each company sets work hours beyond which additional work is voluntary and paid in accordance with applicable laws. Employees must receive adequate compensation to meet their needs and satisfaction from their work. Working conditions must be safe and respectful. The work schedule should allow for at least one day off in seven, adequate rest and meal breaks, and use of sanitary facilities.

Personal safety equipment must be provided with the appropriate training. Explicit information is a requirement whenever hazardous materials or dangerous equipment may be used or stored in the work environment.

Fairness extends to the employer, who should expect a good work ethic from his employees. This includes adherence to all agreed-upon company policies, reasonable care of company property, and respect for clients and vendors.

Employers are encouraged to go beyond the minimal employer-employee relationship by increasing participation and responsibility of employees in the business whenever possible. Wages and benefits should reflect the increased responsibility.

Client relations should be consistent with honest and ethical business practices, a fair price for materials and services provided. Projects should be completed to the client's reasonable satisfaction.

Vendors of the company should be treated honestly and ethically. Payments should be made within the agreed upon terms.

This business philosophy is a guide, not a mandate. Business owners are free to define honest and ethical social conduct, as befits their beliefs and conditions. In any case, all federal, state, and local laws must be complied with.

Purpose of the Standards

The purpose of the *NOFA Standards for Organic Land Care* is to:

- Present the fundamentals of organic land care
- Specify the requirements for professional accreditation by the NOFA Organic Land Care Program
- Specify practices that Accredited Organic Land Care Professionals (AOLCPs) will pledge to abide by when providing organic land care services to the public for fees

The intent of the Standards is not to provide all of the information needed for successful organic land care. More detailed information on organic land care is provided in the 30-hour NOFA Accreditation Course in Organic Land Care, which is offered twice per year, with an annual course in Connecticut in February and additional location in November. Course dates and locations can be found at www.organiclandcare.net.

The NOFA Organic Land Care Program has developed these Standards as part of the process of educating land care professionals about the meaning of the word “organic” and to present our vision of how these principles can be applied to the landscaping profession. Through an education and accreditation program, we hope to make available to the public landscaping services that will meet or exceed the standards presented here. We also hope to educate the public about the meaning of “organic” and the benefits of this option for care of the land around homes, neighborhoods, and communities.

Definition of Key Terms in the Standards

Principles

Many of the sections within the Standards contain a list of fundamental land care principles. These principles form the basis for identifying preferred, allowed, and prohibited practices and materials. While judgments regarding specific practices and materials depend on our current state of knowledge, we expect that the underlying principles will endure well into the future and may serve as a guide when the practitioner encounters a situation not covered in the Standards.

Preferred

Practices and materials the NOFA Organic Land Care

Program finds to be ecologically appropriate and in accord with the goals of organic land care.

Allowed

Practices and materials that are acceptable when needed, but should, where possible, be reduced in favor of the preferred alternatives.

Prohibited

Practices and materials that are not acceptable in organic land care.

A Note About Genetically Modified Organisms

Genetically Modified Organisms are developed from a variety of methods including:

- Cell fusion
- Microencapsulation
- Macroencapsulation
- Recombinant DNA

Organisms developed by these methods are prohibited in organic land care.

Traditional breeding methods that are acceptable include:

- Conjugation
- Fermentation
- Hybridization
- In-vitro fertilization
- Tissue culture

On GMO or GE crops in fertilizers and in compost

Proponents of organic agriculture and organic land care have great concern about the use of genetic engineering technology. Genetically Modified Organisms (GMOs) or Genetically Engineered (GE) Organisms are terms that refer to the process of modifying the DNA of an organism or introducing genes into an organism's DNA that are not normally found within that species as a result of natural evolutionary processes.

As of 2016, more 90% of the corn and soy grown in the United States has been genetically modified. A majority of animal feed and agricultural fertilizers are produced with materials from GE crops. This same case can be made for food waste composting. There is a background level of pesticides and potentially of GE material in

conventionally grown food that gets composted. Some of the poultry litter fertilizer contains materials that we would rather not see, as well.

Many people believe that the use of fertilizers that contain or were made from GE materials should not be allowed by the NOFA Standards for Organic Land Care. That said, it is important to note that all materials are not an equal swap when seeking nitrogen, phosphorus, or potassium to aid fertility. For example, at this time, it seems there is no equal replacement for corn or soy, as a means of delivering nitrogen using grain-sourced proteins. Therefore, it is acknowledged that background levels of undesirable material may exist since many different materials that are regularly used as ingredients in organic fertilizers. It should also be noted that when GE materials are composted, it is unknown, at the time of printing, how the breakdown components of composted materials and fertilizers might affect soil organisms.

Due to these constraints (the lack of suitable alternatives and the issue that organic and non-organic materials are regularly mixed when creating compost), the NOFA Standards committee reluctantly "allows" fertilizers which may contain GE material. This allowance is only because prohibiting them at this time would result in a significant shortfall of materials available to produce adequate amounts of organically-based fertilizers and amendments. The "preferred" approach would be to check sources and ingredients to ensure no GE or pesticide treated ingredients were included.

Emergency Non-Organic Rescue Treatment

As one moves forward in a transitional or organic program, it may become necessary to intervene with a product for control of a particular pest if all reasonable efforts within an Organic IPM program have failed. It is acknowledged that from time to time situations present themselves that call for intervening action that normally would not be incorporated into an organic program. It is far preferable to react to pest pressure than it is to preemptively apply even allowed pesticides.

When a situation arises that could create economic or unreasonable aesthetic injury an application may be made during or after transition that would allow for the inclusion of a material within the framework of a sound organic program.

- When a situation presents itself in the form of pest pressure (insect, weed, or disease) that threatens the stability of the system with an end result of potential economic injury, documentation of the incident or situation is required.
- Any rescue treatment can only be allowed after having a discussion with and receiving approval from the client.
- All organic strategies that have been employed in the management of an organic IMP system must be documented.
- This documentation needs to include the underlying problem(s) (ex. insect, weed, or disease) and include the expectations after control(s) have been attempted.
- A sound organic program should be in place to begin to correct the problem(s) so that the symptom(s) does not reappear.

This intervention will come from an allowed list of both US EPA registered materials that are OMRI approved or from the list of US EPA “25b” minimum risk pesticides. For the latest information on the “25b” lists (administered and approved by each state), please visit <http://organiclandcare.net> and search for “25b” list.

If no material on this list is able to manage the insect, weed, or disease, a personal decision needs to be made on whether a company or person chooses to move to synthetics.

If it appears that the accepted organic product list does not include a material to alleviate the undesirable symptom, a decision might be made to use non-allowed synthetics. There are some synthetics that mimic natural compounds and some synthetic agents that do not pose significant issues. Unfortunately, they cannot be separated from the more general category of synthetics.

That being said, the decision to use synthetic materials is understood by NOFA OLC as something that could be an option at personal discretion. As an organization, we feel that we cannot embrace synthetics and at the same time maintain organic integrity.

If a decision is made to use synthetics, it should be understood that it is a decision that is outside of the NOFA Standards for Organic Land Care, 6th Edition.

Once these materials are used, an organic property now becomes a transitional property. The use of a synthetic material will not jeopardize any individual’s standing as an AOLCP.

As part of this decision detailed records must be kept including:

- Plant species affected
- Target pest
- The trade name of the material
- The active ingredient
- The rate used
- The timing of the application
- Date of application or applications
- The volume of material used
- The amount of area covered

NOFA Organic Land Care Standards and the National Organic Program

The National Organic Program (NOP) is a marketing program housed within the USDA Agricultural Marketing Service that has developed national organic standards and established an organic certification program to assure consumers that agricultural products marketed as organic meet consistent, uniform standards. The now familiar green and black “USDA Organic” emblems appear on foods certified under this program. The *NOFA Standards for Organic Land Care* came originally from the CT and NOFA/Mass agricultural standards, and were developed before the NOP was in effect. On some issues the Standards have been modified to come closer to the NOP (including resolving differences about pest management materials), but on other issues we have chosen to differ. In some ways we are more lenient, and in some ways we are stricter.

Some specific differences:

- Emergency Non-Organic Rescue Treatment: There is no such provision in the NOP.
- In these Standards, we use the categories Preferred, Allowed, and Prohibited. The NOP categorizes materials as Allowed or Prohibited, but has restrictions on the use of many materials that are allowed. For example, materials for management of crop pests, weeds, and diseases are allowed only if a series of non-chemical methods have been found to be insufficient and if the materials are included in the organic system plan filed by the grower.

The NOP was developed for a very different purpose than were these Standards. The purpose of the NOP was to set legally enforceable standards that would be used by accredited organic certifiers to determine which agricultural products could bear the word “organic.” The purpose of the *NOFA Standards for Organic Land Care* is to provide the educational basis of a voluntary program for land care professionals to apply the practice of organic land care to landscapes where people live. These Standards include principles, background information, and some how-to information that are not an element of the NOP standards.

The NOP was developed to set standards for organic agricultural production. In general, agricultural systems require more frequent and intensive intervention in order to provide a regular yield of marketable products than is needed in organic land care. Successful organic land care must satisfy the needs and desires of the client, but there are often much greater opportunities to work toward a sustainable, diverse ecological system than in agriculture, and we try to present those opportunities in these Standards.

For more information on the National Organic Program, see www.ams.usda.gov/AMSV1.0/nop.

Accreditation by the NOFA Organic Land Care Program to Provide Organic Land Care

The NOFA Organic Land Care Program operates an Accreditation Program (through CT NOFA) for Accredited Organic Land Care Professionals (AOLCPs). Professionals take an approved 30 hour accreditation course, pass an exam, and pledge to provide organic land care services according to the *NOFA Standards for Organic Land Care* for their clients who request these services. There are currently over 500 accredited professionals in 20 states. CT NOFA staff oversee the NOFA Organic Land Care Program. Accreditation provides access to continuing education courses, referrals, networking, newsletters, publicity, media interviews, and a business listing in an online searchable database found at organiclandcare.net/aolcp-search.

Accredited Organic Land Care Professionals are allowed to use a NOFA-approved logo on their printed marketing materials for the year in which they are accredited. For example, the logo might appear on business cards, on brochures, on websites, in advertisements, on uniforms,

5 | NOFA Standards for Organic Land Care

and on company vehicles.

Accreditation Requirements

The following steps are required to become a NOFA Accredited Organic Land Care Professional (AOLCP):

- Complete the 30 hour NOFA Accreditation Course in Organic Land Care
- Demonstrate knowledge of and skills in organic land care by earning a passing grade on the Accreditation Examination
- Sign a pledge to follow the tenets set out in the Standards for all clients who request organic land care
- Pay the Accreditation Fee

Maintaining Accreditation

Accreditation will be for a period of one calendar year and is renewable annually. To remain accredited, an AOLCP must obtain four approved continuing education units (CEUs) and pay a re-accreditation fee each year. A list of approved CEUs is maintained on the NOFA Organic Land Care Program website at www.organiclandcare.net. Potential credit opportunities can be submitted online at <http://www.organiclandcare.net/accreditation/creditapproval>

Accreditation may be withdrawn if CT NOFA staff and the CT NOFA Board have determined that any land care professional has misled clients about organic practices or failed to adhere to the Standards in providing services to clients requesting organic land care.

There are provisions for renewing a lapsed accreditation. Please refer to the NOFA Organic Land Care Program website, www.organiclandcare.net, for more information.

Disclaimer

The NOFA Organic Land Care Program works to foster professional competency in the area of organic landscaping and protect the public interest in responsible use of land care products and land resources. We publicize the list of AOLCPs so that people interested in having their properties managed organically can more easily find trained professionals. AOLCPs have satisfied the accreditation requirements listed above, but neither the NOFA Organic Land Care Program nor CT NOFA makes any further claims to the quality or cost of work performed by an AOLCP, nor are they responsible for any damages incurred in procuring or using AOLCP services.

Split Businesses

Some businesses may choose to only offer organic land care services. In cases where a business offers both organic and non-organic land care services, referred to here as a split business, it is crucial that clients understand clearly what type of land care services they are receiving.

The Guidelines are as follows:

1. Printed business materials and advertising that are directed at the public must clearly distinguish the organic and non-organic divisions of the business.
2. The NOFA logo must NOT be displayed on vehicles or equipment used to administer non-organic treatments.
3. Any application equipment used for organic treatments must NOT also be used for non-organic treatments.
4. Any materials used in organic land care practices must be stored separately from nonorganic materials to prevent cross-contamination.
5. A company can exclusively provide organic services and can use the word organic in their business name, such as “Organic Lawns, Inc.”
6. A company may provide conventional services and have an separate division that offers soley organic services. In this case, the company CANNOT use the word organic “organic” in their company’s name.

Standards Review and Revision Procedures

The Standards were researched and written in 2000-2001 by a multi-state volunteer group of practicing land care professionals, scientists, and concerned citizens, with assistance from technical advisors. The Standards – and especially the preferred/allowed/prohibited practices and materials – are intended to be reviewed periodically by practitioners, NOFA staff, and an ad-hoc committee charged with Standards Review, and amended as appropriate. The current revision is the sixth revision of the Standards.

Suggestions for changes to these Standards are welcome. Land care professionals, scientists, extension educators, government officials, and others are invited to submit suggestions in writing to the CT NOFA office. New materials, new products, and new information on practices will be considered at the time of Standards revision.

SITE ANALYSIS, DESIGN, AND MANAGEMENT

As an Accredited Organic Land Care Professional, the approach to your work needs to be from an ecological perspective. It is important to understand the site before any changes are proposed. The first step in the process should always be understanding through observation. Whether the site is suburban, urban, or rural, it is vital to recognize the existing ecological functions and the interdependent relationships which occur on that particular parcel of land. This careful observation will provide insight and help guide any new design work.

Using the principles in these Standards as a guide, **Site Analysis** is the observation of the key elements of a site, coupled with an understanding of how these elements affect the relationship between organisms (people, plants, animals, microscopic soil life) and the site. Site Analysis is the primary discipline used to determine appropriate land use – including plant selection and placement, construction and placement of hardscape elements, and in some cases, site modification to create particular ecosystems.

Site analysis is the primary tool used by an AOLCP to determine appropriate changes to existing sites. The checklist below provides a summary of the key components to be observed and recorded during a site analysis. The components may be different depending on the site. For example, Utilities may be more relevant to a large urban site versus an individual suburban, residential site, however the approach in either case is the same.

Checklist for Site Analysis:

Physical Elements

- Topography
- Vegetation
- Soil
- Hydrology
- Climate

Existing Organisms

- Microscopic
- Insect
- Animal
- People

Cultural Elements

- History
- Current Use

- Adjacencies
- Circulation
- Views
- Utilities
- Nuisance (noise, odor, etc.)

Design is the intentional and creative application of the principles outlined in these Standards to develop, engineer, and manage landscapes sustainably and in an ecologically sound manner. It employs the disciplines of ecology and sustainability, coupled with artful implementation, to create landscapes that can be managed organically.

- A key goal is to design landscapes that are regenerative, encouraging Nature's healing processes to restore ecological balance in disturbed landscapes.

Management refers to the holistic care of a landscape before, during, and after installation in a manner that promotes and sustains healthy soil, micro and macro-organisms, plants, and people. It utilizes recognized organic methods and materials, and also innovation and experimentation, so long as they conform to the principles set forth in these Standards.

Principles of Management:

- A goal of organic management is the gradual decrease of inputs as the landscape is guided toward sustainability.
- A goal of organic management is to maintain the landscape in a manner that will enhance its habitat value for all inhabitants, human and non-human.

Preferred

- Site analysis that includes: special attention to variation in microclimates; evaluation of sunlight availability and degrees of shade, soil characteristics (see Soil Testing, page 10), air circulation, water flows, and temperature variations; and observations of plants and animals, current land use, and features of the surrounding landscape
- Understanding not only the site delimited by the property lines but the bioregion in which it is located
- Use of native plants whose characteristics are ecologically appropriate to the site

- Leaving established ecosystems intact (except where invasive or harmful plants exist)
- Producing food (vegetable gardens, edible landscapes)
- Restoring, protecting, enhancing, and creating ecologically appropriate wildlife habitat (e.g., riparian buffers)
- Establishing buffers to protect organic sites from neighboring non-organic sites
- Designing landscapes that enhance the principles of ecology and sustainability (e.g., reducing the amount of space devoted to lawns)

Allowed

- Modifying existing habitats, within the guidelines of these Standards, where a new landscape design is desired
- Use of non-native plants whose characteristics are ecologically appropriate to the site

Prohibited

- Breaking local, state, or federal laws regarding wetlands and buffer zones
- Using plants that are inappropriate to the site or that require extraordinary inputs and efforts to keep them alive
- Modifying a site in a way that results in considerable harm to the environment
- Use of invasive plants
- Designing and managing a site in ways that violate these Standards

SOIL HEALTH

The foundation of organic land care is knowledge of and proper care for the soil. Soil tests, along with site analysis, allow the land care professional to select and implement practices that maintain or increase soil life and vitality and thereby enable the soil to support a vigorous plant community. A healthy soil is free of crusts, compaction, pesticides and other toxins, salt buildup, and excessive erosion, and contains sufficient organic matter and nutrients, in proper balance, to support a large and active population of native organisms.

The community of organisms that inhabits the soil is known as the soil food web. The soil food web consists of such familiar earth dwellers as worms and insects but also the countless microscopic creatures, bacteria, and fungi that inhabit every spoonful of soil. The benefits of a healthy soil food web are many. It forms protective layers around roots to keep pathogens at bay, helps plants obtain nutrients from the soil, breaks down toxic compounds that inhibit plant growth, improves disease suppression, and builds soil structure, making it easier for roots to grow and obtain nutrients and water.

In natural systems, organic matter - provided by decaying roots and stems and, in forested areas, the autumn leaf drop - cycles in place. A thriving microbial community digests and breaks down this organic matter, releasing nutrients back into the soil. The organically managed landscape retains and recycles organic matter, to the extent that the client's needs and the situation permit. On-site composting is a means to this end, as is shredding or chipping organic material on a property and allowing it to compost in place. By closing the nutrient cycle in this way, the need for external inputs is minimized.

Organic soil amendments may be needed to help balance a soil's chemistry, stimulate its biology, and restore its physical composition. Such amendments may also be required to support the growth of a typical lawn, which has extraordinary nutrient needs because it is maintained in an unnatural way - relentlessly mowed and kept green as long as possible.

In an organically managed landscape, soil fertility is enhanced by feeding the soil, not the plant. Carbon and nitrogen are applied to the soil in the form of manure, compost, blended organic fertilizers, and cover crops, and the soil food web breaks these organic materials down into the nutrients that plants need. Horticultural
9| NOFA Standards for Organic Land Care

methods that short-cut this natural process by supplying synthetic nitrogen, phosphorus, and potassium (NPK) directly to plants lead to damaged soils and weak root systems, making the plants more susceptible to insects, disease, and drought. Repeated, excessive application of synthetic fertilizers may also inhibit the development of mycorrhizae - symbiotic fungi growing on or around plant roots that help to gather nutrients beyond the range of the roots themselves. Eventually the soil structure collapses and the soil becomes infertile. To revive dead, compacted soil, it may be necessary to apply compost to reintroduce soil life.

A carefully managed soil-building program that increases soil organic matter and humus gives many benefits. It recycles nutrients, improves water retention, balances minerals, and buffers pH. In addition to compost and manure, other amendments, such as root stimulants, rock dust, and beneficial microbes, may be indicated based on soil test results.

Principles

- There are two approaches to matching soils and plants:
 1. *We can maximize the diversity of soils and plants and minimize the need to alter the soil by leaving the soil alone as much as possible and choosing appropriate plants for that soil, site, and microclimate; or*
 2. *We (or the client) can decide what plants are desired and alter the soil and site to make them suitable for the desired plants.*
- The first choice is the more desirable because it minimizes our effects on the environment, and thus the potential for harm from our interventions. In either case, we must avoid practices that impair soil health and the health, diversity, and functioning of soil organisms.
- Organic land care follows a holistic approach to plant health, nourishing soil life instead of feeding plants directly. This is accomplished by increasing organic matter in the soil, balancing nutrients and pH, and increasing soil life through the judicious use of biologically active materials such as compost and compost tea.
- To reduce our ecological footprint, we emphasize

the cycling of nutrients on site, supplemented as needed by local, renewable, sustainably harvested materials, and limit our use of materials that are mined or transported from far away to those that are necessary and not obtainable in any other way.

- Soil tests are essential to gain specific information about the soil, and must be performed before any soil alterations can usefully be made.
- We must minimize or eliminate any risk of contamination of soil or water with toxic substances or excessive nutrients, whether they are added directly, as with fertilizers, or simply allowed to come into contact with the soil. We utilize natural remediation methods, where possible, to cleanse the soil of contaminants.

Soil Testing

Soil testing provides essential information about soil texture and structure; the levels of minerals, nutrients, organic matter, and other essential components; and the presence of soil organisms. Core samples are taken to determine the depth, structure, and texture of the topsoil layer and basic characteristics of the subsoil layer. A standard soil test is used to determine soil pH (acidity/alkalinity); the percentage of organic matter in the soil; and any nutrient or mineral deficiencies, excesses, or imbalances. A more comprehensive soil bioassay can evaluate the presence and balance of soil organisms such as fungi, bacteria, nematodes, and protozoa.

Taking soil samples and preparing them for shipment to a lab is not difficult and does not require special tools. Each lab (see Appendix III, page 61) provides complete instructions and specifications that must be followed to obtain accurate results. It is important to note that a soil test will yield meaningful results only when a representative sample is collected and prepared for each area of interest (the vegetable garden, the lawn, the perennial bed, around a tree, etc.). There is time and effort involved in this process, and lab fees to pay as well, but the knowledge gained is invaluable to you and your client.

Do not be tempted to purchase a soil test kit from a garden center or home improvement store. Such kits typically show pH and nutrient levels through colorimetric reactions (placing a soil sample into a solution causes the solution to turn color), and their results are only as accurate as one's visual acuity and the print quality

on the reference card. Homeowner-grade pH meters are also highly suspect because their readout is analog and calibration against standard buffer solutions is not possible. Recently introduced digital pH meters, such as the Hanna® pHep 5, can be both accurate and precise, but only if the person doing the testing has been trained in their proper use.

Soil testing isn't just a good idea, it is a requirement of proper land management. Neither experience, intuition, nor received knowledge, as valuable as they may be, provides sufficient basis for determining the need to apply amendments or fertilizer, or the amount required to correct a perceived deficiency or imbalance. The only way to know what a soil requires is to test it. The only way to determine how to correct a problem with a soil is to test it. Throwing fertilizer around without benefit of a soil test is malpractice - by any standard.

Preferred

- Performing an initial soil test, then retesting every three years thereafter
- Obtaining separate soil samples from each type of microclimate (sun/shade, wet/dry, etc.) to ensure accurate representation of all soil conditions on a site
- Sending samples to a professional or government soil testing lab for analysis and organic recommendations, and for a soil bioassay, if desired (see Appendix III, page 61, for a list of soil testing laboratories)
- In cases where the soil test laboratory recommends non-organic amendments or fertilizers, adjusting those recommendations to meet the requirements of these Standards
- Keeping records for each site, including name and location, date of initial test, and preexisting conditions, and a copy of the soil test results. Also maintain a record of any applications and a summary of any changes observed.

Allowed

- Applying amendments after planting, following soil test results
- Measuring soil pH using a digital pH meter calibrated against standard buffer solutions. Individuals performing such tests must be trained in the appropriate collection of soil samples and

calibration and use of the meter, as well as the standard testing protocol.

Prohibited

- Using a homeowner-grade colorimetric soil test kit or analog pH meter to determine application of soil amendments or fertilizers
- Using tools and containers for soil testing that retain remnants of other matter. Any contaminants may taint the results. Tools and containers must be clean.
- Amending the soil or fertilizing with nitrogen, phosphorus, or potassium without the guidance of a soil test
- Following soil test recommendations that are prohibited in these Standards

Toxic Elements in Soil

Many elements occur naturally in soil as inorganic ions (charged species) and at least 18 of them are known to be plant nutrients. Of these elements, approximately half are required by plants in very small quantities and are described as trace or micronutrients. Human activity can adversely affect soil, either by the incorporation of toxic elements such as mercury, lead, and cadmium or by increasing the proportion of necessary trace elements such as copper or zinc to toxic levels. Modes of incorporation into soil can include the use of pressure-treated wood, sanding or scraping of paint containing lead on nearby structures, use of dirty fill, past use of pesticides containing lead or arsenic, application of industrial or domestic sludge (also called sewage sludge or biosolids), smokestack emissions, and past use of leaded fuels. Testing the soil for heavy metals is strongly encouraged on potentially contaminated sites before growing food or creating play areas for children.

Toxic elements, once introduced to the soil, have a tendency to persist. Preventing the contamination of soils is critical because remediation of polluted soil can be both costly and time consuming.

If there is reason to believe a site has been contaminated, proper management begins with a soil test to determine the level and type of contamination, followed by consultation with a specialist trained in management and remediation of toxic elements in soil. Once the test results are known and fully understood, the proposed remediation plan must comply with all pertinent federal,

state, and local statutes.

Preferred

- Limiting soil disturbance at sites suspected or known to be contaminated (such as those bordering heavily-traveled roads, near gas stations, and in industrial areas) to reduce human exposure
- Maintaining thick turf, dense evergreen groundcover, or impenetrable vegetation on contaminated sites to prevent children from digging and to reduce tracking of contaminated soil into buildings
- Working in collaboration with a phytoremediation or mycoremediation specialist to determine how to use specific plants or fungi to absorb toxic elements from a contaminated site. Consult with local authorities to make sure that the plant or fungal material is disposed of properly.

Allowed

- Disturbance of contaminated sites, provided no edible and/or berrying plants are installed, and there is no migration of contaminants to adjacent sites
- Covering contaminated soil with sod or with plastic sheeting followed by a layer of organic mulch or gravel
- When planting on a contaminated site, sealing the site with plastic sheeting, then adding an appropriate amount of compost or soil for the plants to grow in

Prohibited

- Installation of edible and/or berrying plants
- Removing contaminated soils, except for regulated disposal
- Allowing runoff from disturbed contaminated sites to reach uncontaminated areas

Materials in Contact with Soil or Plants

Building materials, masonry, edgings, landscape fabrics, and other materials that come in contact with soil or plants should be free of harmful substances such as toxic metals, pesticides, and toxic chemicals. Pressure-treated wood products that contain chromated copper arsenate (CCA) are of special concern. These products are no longer sold for residential use, but if they have been used in the past, toxic residues may still be present.

Studies have shown that high amounts of CCA, which is extremely toxic, can be released from the wood in most soils found in the Northeast.

Preferred

- Untreated, rot-resistant wood, such as cedar, white oak, or black locust, from sustainably harvested sources
- Wood alternatives such as recycled plastic and plastic and wood fiber composites, provided they do not contain polyvinyl chloride (PVC)
- Masonry (stone, bricks, etc.)
- Non-galvanized or stainless steel
- If pressure-treated wood is present, testing the soil for arsenic, chromium, and copper before planting food crops or disturbing the soil

Allowed

- If chemically treated wood already exists on a site and cannot be removed or the client is unwilling to remove it, coating the wood with paints or stains formulated for such use, such as polyurethane, acrylic, and spar varnish. Re-coat as required.
- Newspaper printed with black ink, used under a layer of mulch to suppress weeds
- Plastic and nonwoven geotextile fabrics that do not contain polyvinyl chloride (PVC)
- Synthetic burlaps, if removed completely at time of planting

Prohibited

- All types of chemically treated wood, burlap, stakes, and twine
- Chemically treated paper and cellulose mulches
- Newspaper printed with color inks and inserts printed on glossy paper
- Plastic and nonwoven geotextile fabrics that contain polyvinyl chloride (PVC)
- Synthetic burlaps
- Creosote- or tar-treated wood (such as railroad ties)
- Petroleum-based wound dressings
- Galvanized steel
- Mulch made from ground-up rubber tires

INLAND WETLANDS AND WATERCOURSES

Inland Wetlands may be transitional areas between open water and dry land or they may be isolated areas away from open water. They are found in uplands, on the top of hills, the side of hills, in valleys, and along watercourses such as rivers, streams, and ponds or lakes. Wetlands form in areas dictated by landscape position in relation to the underlying soil and bedrock and regional drainage patterns. The formation and development of wetlands may also be influenced by wildlife activity, e.g., beavers.

Numerous ecological functions and values are attributed to wetlands: water quality and water quantity, flood control, habitat and biodiversity, groundwater recharge, storm water runoff, reduction of soil erosion, aesthetics, and production of natural products such as timber, fish, cranberries, and wild rice.

Inland wetlands include semi-aquatic areas and also terrestrial areas that are subject to a high, or fluctuating, water table for periods each year that are sufficiently long to cause soils to develop hydric properties and support vegetation that is adapted to life in saturated or poorly drained soil. The specific types of wetlands vary considerably around the United States, from riparian wetlands along rivers to isolated depressions surrounded by dry land, from acid or calcareous bogs to wetlands dominated by shrubs, and from wet meadows to hardwood swamps, inland marshes, and vernal pools.

Care must be taken during land management and landscaping to avoid stream channel degradation, sedimentation, and backyard wetland damage due to filling, excavating, dumping yard waste, or mowing up to the edges of wetlands or ponds.

Most states now have strong inland wetland protection laws. State laws vary but usually require accurate and detailed identification and delineation of wetland boundaries by a credentialed professional. In Connecticut, the law stipulates that this process be performed by a soil scientist. Laws also regulate certain types of activities in wetlands and also in upland review areas adjacent to wetlands. Such activities may include landscaping, as well as paving, building, etc. Of particular concern is the construction or removal of dams, which may change stream flow and velocity and result either in downstream flooding or the deprivation of water to downstream wetlands. Permits are usually required for any activity within wetlands or upland review areas. Possible exceptions

may include simple landscape maintenance that does not require machinery. The Army Corps of Engineers also has jurisdiction over wetlands and watercourses in the United States, and certain types of projects may require an ACOE permit.

Principles

- We must learn about the different types of wetlands that may occur in the bioregion where we live and work, and their functions and values.
- We must become familiar with, and develop an understanding of, the local, state, and federal regulations that govern inland wetlands and watercourses. All wetlands work must be done in compliance with these regulations.
- We must make every effort to avoid negatively impacting wetlands and strive to protect, maintain, or improve inland wetlands occurring on the properties we manage.

Preferred

- Becoming conversant in and complying with inland wetland regulations and where to apply for permits or receive guidance (town commissions or county or regional boards)
- Consulting with a professional to identify all wetlands and watercourses on a site
- Protecting wetlands during landscaping by following best management practices, which are usually available from state departments of environmental protection
- Advising the client of inland wetland regulations to help him or her avoid violations, which can result in costly fines and expensive remediation projects
- Helping the client work with a wetlands agency to develop a reasonable plan within the law, one that includes prudent alternatives and provides for mitigation actions to restore or replace any wetland areas that might be impacted by the proposed activity
- Adopting landscaping practices that enrich or benefit wetlands - e.g., increasing native plant buffer

plantings around wetlands, ponds, and riparian buffer zones; removing invasive species; building water infiltration gardens; preventing soil erosion and sediment from settling into wetland areas; and stabilizing stream banks

Allowed

- Making site changes to address safety concerns
- Reasonable use of the home grounds by the homeowner in the areas close to the residence, i.e., normal outdoor living areas attached to the home, reasonable recreation areas, access pathways, and garden materials storage
- Creation of vehicle or emergency access across wetlands or watercourses

Prohibited

- Draining or filling of wetland areas
- Any activity in a designated wetland or upland review area without a permit
- Removal of existing vegetation from wetlands or wetland buffers, except invasive species that will be replaced with appropriate natives
- Altering a stream channel by piping, straightening, or otherwise disturbing the natural flow of the watercourse
- Garden waste disposal in a wetland
- Spreading fertilizer or fresh manure in a wetland or upland review area

WATER USE AND WATER QUALITY

Unprecedented fresh water shortages, declining stream levels, and degraded water quality are serious and growing problems in the United States, as they are in much of the world. According to a report by the U.S. Government Accounting Office (2014), state water managers, experts, and research showed that freshwater shortages are expected to continue into the future in the United States. In the report, 40 of 50 state water managers expected shortages in some portion of their states under average conditions in the next 10 years. (<http://www.gao.gov/assets/670/663344.pdf>). Cities and communities that already face tightening fresh water supplies have arrived at their predicament due largely to *one single uncontrolled and excessive water demand: landscape irrigation*. An estimated 50% of United States urban water demand - half of all water going to cities, towns, and suburbs - is pumped onto landscapes, principally lawns, according to the U.S. Environmental Protection Agency.

Today, even “water-rich” Massachusetts, which receives over 40 inches of precipitation annually, faces a long-term water supply deficit despite the fact that its population has been largely stable for over 20 years. On October 11, a Northeast Drought and Climate Outlook Forum was held at UMass Boston and a report was issued to distribute information on this historic drought. They reported that drought conditions had intensified during summer 2016, with extreme drought (D3) being introduced in parts of New York and New England in August. It was the first time that several of these areas had experienced D3 conditions since 1999 when Drought Monitor began to collect data. Extreme drought conditions would be expected to occur on average once per 20–50 years. Portions of New York and New England had been in an extreme drought for 6–10 weeks by October. By February of 2017, drought.gov continued to report drought across the Northeast, which appears to be a new trend which land managers will need to contend with. (<https://www.drought.gov/drought/sites/drought.gov.drought/files/media/regions/regions/Northeast/Northeast-Drought-Forum-Overview-Oct-2016.pdf>, <https://www.drought.gov/drought/northeast>). Water use during the summer lawn-watering season as much as doubles in some suburban towns, suggesting that the growing number of automatic irrigation systems, along with the unprecedented number of new private landscape irrigation wells, which increasingly dominate new developments, towns, and suburbs, are the primary cause of this river stress. Each automatic landscape

15| NOFA Standards for Organic Land Care

irrigation system and private irrigation well commonly pumps hundreds and sometimes thousands of gallons of water a day.

At such excessive rates of water use and abuse in New England and across the United States, is it any wonder why even the most water-plentiful regions in America fear they will one day run out of water?

Principles

- Conservation of both water supply and water quality should be factored into all site design, construction, and management practices.
- All sources of water, including but not limited to municipal water, private ground or surface water, rainwater, and gray water, are valuable and should be conserved in both supply and quality.
- Do no harm that would alter or disturb natural onsite water flows, ponds, groundwater, or other natural water features. Existing natural water features (wetlands, streams, ponds) on or near a property should be identified, and the course of their flow and movement should be left unimpeded and protected from disturbance. All water in its free-flowing state acts in the service of local ecosystems whether or not it is visible to the human eye.
- Know and respect your watershed. Seeming water abundance is never a justification or license to take or use water for nonessential purposes. Lawn and landscape irrigation are nonessential water uses. They should be limited to temporary needs (such as establishment of new plantings) or exceptional situations (such as athletic turf), and should operate as efficiently as possible.

Preferred

- “Right plant, right place” - selecting native and noninvasive exotic landscape plants and lawn grasses that will thrive under local temperature and climate patterns
- Planting at times of year when rainfall is plentiful and the need for irrigation is low
- Rainfall-only irrigation for lawns and landscapes after turf and plant establishment. Native plants

and noninvasive exotic plants and lawn grasses, once they have been established, should not need supplemental irrigation.

- Allowing lawns to go through natural dormancy cycles (i.e., allowing grass to go brown in summer). It is normal for cool-season lawn grasses to go dormant when temperatures rise and water becomes less plentiful in summer. They green up again when temperatures cool and rainfall becomes more abundant. Watering lawns in summer not only depletes an increasingly precious resource, it places undue stress on the grass plants (see *Lawns and Lawn Alternatives*, page 32).
- Using only *proven* water conservation practices and technologies backed up by credible evaluations and rating systems. Exercise caution when considering the water-saving claims of manufacturers, product vendors, and trade groups. Demand verification by independent third-party labs.
- Pervious surfaces that allow water to pass through to the soil underneath rather than run off. Many types of permeable materials are available for terraces, sidewalks, walkways, and driveways.
- Directing runoff (such as from roofs) to pervious areas, such as natural infiltration areas and vegetable gardens
- Restoring and maintaining natural buffers along watercourses and wetlands in accordance with local, state, and federal laws
- Preventing contamination of stormwater with cleaners, solvents, waste materials, and other pollutants. See “Environmental Best Management Practices Guide for Small Businesses” in the Bibliography, page 58. See EPA’s *WaterSense Labeled New Home Irrigation Audit Checklist* for acceptable design and installation criteria for irrigation systems, also in the Bibliography.

Allowed

- Temporary hose irrigation for the establishment of turf and landscape plants
- During particularly dry periods, manual watering with a hose to sustain garden vegetables and fruits and to keep important landscape plants from dying, as allowed by local watering ordinances

- Limited permanent irrigation systems, with the following restrictions:

- o All permanent irrigation systems must meet water efficiency standards, e.g., be leak-free, have high distribution uniformity (DU), and meet the criteria for acceptable irrigation system design (new and renovated systems) and maintenance (all systems) according to the US EPA WaterSense® Program’s *Final Specifications for Single-Family New Homes*, as described in the *Resource Manual for Building WaterSense Labeled New Homes, Section III. B., Irrigation Systems (4.2)* (see www.epa.gov/watersense/docs/newhome_builder_resource_manual508.pdf) and the *WaterSense Labeled New Home Irrigation Audit Checklist* (see www.epa.gov/watersense/docs/home_irrigation-audit-checklist508.pdf).
- o Property owners with automatic irrigation systems must be taught how to set the controllers and reprogram them to account for changes in seasonal temperature and rainfall patterns and plant demands.
- o A working rain shut-off valve must be installed on automatic irrigation systems. Functioning must be checked at least annually.
- o “Smart” weather-based irrigation controllers (WBIC) may only be used under the following conditions: The irrigation system must meet water efficiency standards, e.g., be leak-free, have high distribution uniformity (DU), and meet the criteria for acceptable irrigation system design (new and renovated systems) and maintenance (all systems) according to the US EPA WaterSense® Program’s *Final Specifications for Single-Family New Homes*, as described in the *Resource Manual for Building WaterSense Labeled New Homes, Section III. B., Irrigation Systems (4.2)* (see www.epa.gov/watersense/docs/newhome_builder_resource_manual508.pdf) and the *WaterSense Labeled New Home Irrigation Audit Checklist* (see www.epa.gov/watersense/docs/home_irrigation-audit-checklist508.pdf).
- o To prevent runoff, irrigation system run times must not exceed a site’s soil water-holding capacity and plant needs.
- o Moisture sensors are only beneficial for saving water when they are properly installed and maintained according to the manufacturer’s

directions and used with a well-designed automatic irrigation system.

- Minimal use of petroleum- and chemical-based plastics - such as pipes, barrels, and liners. Contact with water and/or sunlight causes plastics to degrade and release plasticizers, endocrine-disrupting chemicals, and other nonorganic materials that can leach into water and soil and enter the soil food web. When plastics must be used, downsize the area and volume of material whenever possible.
- Rainwater harvesting, under the following conditions:
 - o Rainwater collected for irrigation shall not be stored or harvested in volumes larger than are needed to irrigate vegetables, fruits, and nut trees, and essential landscape plants. Water collected from rainwater shall not be hoarded or stored in excess.
 - o Rainwater applied to the landscape shall be in accordance with all local drought and water conservation watering rules and restrictions, even if they only apply to potable (municipal) water.
 - o Rainwater shall not be applied to non-essential areas, such as lawns.
 - o Rainwater collection systems should be properly maintained to prevent mosquito breeding and water contamination.
- Use of gray water or reclaimed water for irrigation of non-edible plants, as permitted by law (check local and state health codes)
- Limited impervious surfaces, where necessary. Impervious surfaces include driveway blacktop, building structures, soil compaction, and loss of vegetative cover. They cause precipitation to run off to storm drains and streams, thereby reducing the amount of rain water that can percolate through the soil to recharge groundwater.

Prohibited

- Irrigation practices that waste water, such as causing water to run-off onto hardscape (e.g., sidewalk, driveway, nonvegetation areas), puddle, or foster disease or fungal growth on lawns and plants
- Use of broken or leaking irrigation systems. Broken systems include improperly wired or installed systems and improperly scheduled irrigation runs (e.g., irrigation during rain, for excessive run times, etc.).
- Automatic lawn and landscape irrigation systems that are not adjusted as needed to account for changes in seasonal temperature and rainfall patterns and plant demands
- Any misuse of water that causes flooding or erosion problems (e.g., improperly designed or maintained irrigation systems, water features, or rainwater harvesting systems)
- Gray water or other reclaimed water that does not meet local, state, and federal water quality and public health and safety standards
- Addition of synthetic chemicals of any kind to the water used on an organically managed landscape or property
- Draining or filling of wetland areas
- Synthetic turf, plants, or mulches. Synthetic materials, such as recycled tires, may contain lead, cadmium, and other hazardous compounds that can contaminate surface or groundwater.

ENERGY, POLLUTION, AND CLIMATE CHANGE

The impacts of human activity on environment and climate change are now well established. Efforts to reduce environmental pollution and mitigate climate change focus largely on reducing fossil fuel consumption and waste and increasing the use of renewable energy sources. The land care profession has an important role to play. The majority of land care businesses use copious quantities of petroleum for transportation and for powering equipment, and generate millions of pounds of non-recyclable solid and toxic waste. This has implications not only for our environment and climate, but also for our health.

Although the land care profession calls itself “green”, the color refers to chlorophyll, not to sustainability. The most obvious impacts relate to fuel-powered land care equipment.

- **Fuel Consumption:** Each year in the United States, lawn mowers alone consume more than 1 billion gallons of gasoline.
- **Greenhouse Gases:** Each year in the United States, land care equipment produces more than 20 million tons of carbon dioxide, contributing to climate change.
- **Pollutants:** In addition to greenhouse gases, exhaust from land care equipment produces millions of tons of toxic and carcinogenic compounds each year that pollute our air, water, and soil. These compounds include volatile organic compounds such as benzene, 1,3 butadiene, and formaldehyde – all leading carcinogens; nitrogen oxide; carbon monoxide; and fine particulate matter. Ozone, formed by volatile organic compounds and nitrogen oxide in warm seasons, and fine particulate matter are well established risks for serious health problems, including heart disease, stroke, and cancer. Especially vulnerable populations include equipment operators, children, and seniors. Studies have also shown these pollutants adversely affect plant health. Reducing the use of fuel-powered equipment can improve the health of humans, pets, plants, and the environment.
- **Noise:** Also considered an air pollutant, land care equipment can generate high levels of noise in ranges considered to be harmful to health and hearing.

In general, noise from fuel-powered equipment is louder than electric-powered equipment.

- **Toxic and Non-Recyclable Solid Waste:** Maintenance of fuel-powered land care equipment requires regular replacement of solid parts such as spark plugs, belts, and filters, and the use of toxic chemicals and solvents such as fuel oil, lubricants, detergents, and degreasers. Used products, containers, and chemical residues wind up in our soil, water, and landfills. Reducing the use of fuel-powered equipment means less energy is used to produce, transport, and dispose of maintenance products and fewer products are incinerated. Carbon dioxide emissions and environmental pollution are reduced.
- **Fuel Spillage:** Spillage is a significant problem when using fuel-powered equipment, polluting soil and waterways. The US EPA estimates that 17 million gallons of gasoline are spilled each year from re-fueling lawn mowers alone; over 50% more than the amount spilled by the Exxon Valdez. The American Green Zone Alliance (Woodland Hills, CA) estimates several million more gallons are spilled each year from re-fueling handheld equipment.

A less obvious source of negative environmental impact is the “embodied” energy found in landscaping materials. Embodied energy is the energy used to create a product and move it to the point of sale or use. The production of synthetic fertilizers requires huge amounts of energy, and trucking the heavy bags requires yet more. Synthetic nitrogen fertilizer is particularly damaging, contributing to CO₂ emissions in its production and transportation, creating the greenhouse gas NO₂ in its use, and disrupting the global nitrogen cycle. In addition to the energy used to make and transport synthetic pesticides, many of the formulations and “inert” ingredients are composed of compounds derived from petroleum. Even tap water embodies energy, whether it is pumped from the ground or delivered under pressure through an intricate system of pipes - after being treated with chemicals that also embody energy.

The soil is an important carbon sink. An enormous quantity of carbon is stored in the soil, as humus, organic matter, and in living organisms.

Much of the carbon in the atmosphere comes from three places:

1. being released from the soil as a result of tillage
2. leaving the soil bare
3. chemical use

The best way to return carbon to the soil is by keeping the soil covered with a diversity of living plants, avoiding tillage, and avoiding synthetic chemical fertilizers and pesticides. While adding organic matter to the soil, or leaving nature's organic matter in its place, will increase soil carbon in the short run, the liquid carbon that plants exude from their roots seems to result in more long-lasting carbon storage in humus, and in deeper and less volatile carbon storage. For more information, see *Soil Carbon Restoration: Can Biology do the Job?* by J. Kittredge at nofamass.org/carbon

Although it may be impractical for some land care businesses to go cold turkey and stop depending on fossil fuel energy entirely, there are ways to significantly reduce its use.

1. Commercial grade, cordless, battery powered electric equipment is now available and can replace gas-powered equipment.
2. Gas-powered equipment can be employed more judiciously.
3. Local materials can be preferred to those collected or manufactured hundreds of miles away.
4. Compost made on site can be applied instead of synthetic fertilizers.

The organic land care professional needs to operate a successful business while focusing on larger issues. These two concerns are not incompatible. Minimal use of fuel-powered equipment and the use of local materials can do more than help save the planet; they can also improve health, quality of life, and the bottom line.

Principles

- Energy use, environmental pollution, and climate change are critical issues at this time in history. Changes in traditional fuel-intensive maintenance and landscaping can have a major positive impact on environmental quality, health, and climate.
- Organic land care practitioners consider the embodied energy of the materials and resources

used in their work to minimize the total energy used to make, deliver, and dispose of materials.

- Organic land care practitioners should strive to minimize or eliminate the use of fossil fuel-powered equipment to reduce energy use, greenhouse gases, harmful noise and pollution, spillage, and sources of waste.
- Organic land practitioners should seek to reduce energy use through the design of their offices and workshops and the scheduling of jobs.
- Landscape design can have a significant effect on the maintenance which a landscape requires. Landscape plantings can be designed to reduce the amount of energy required to heat and cool houses and other structures. Shade trees can be planted to block the summer sun; evergreens can be sited to deflect prevailing winter winds.
- Soil is an important carbon sink. Undisturbed soil which is covered with a wide diversity of plants, especially perennials, and not treated with synthetic fertilizers and pesticides, can capture and store a great quantity of carbon that is currently in the atmosphere.

Preferred

- Using quiet, emissions-free electric and/or manual tools and equipment whenever possible
- Protecting workers and others from harmful noise and pollution; adhering to manufacturer guidelines on proper use
- Keeping equipment and tools maintained and in good working condition
- Designing landscapes that require less management (e.g., planting slow-growing plants below house windows to reduce the need for shearing and foregoing fertilizer on lawns to reduce the need for mowing and watering. Natural areas are less energy intensive than lawns.)
- Considering maintenance energy requirements as well as installation energy requirements in all designs
- Using locally produced materials and plants
- Using on-site or local materials for design, construction, and maintenance

- Striving for a closed system on a property - for example, creating and using compost made from materials found on site
- Using manual tools and equipment
- Emphasizing the cultivation of edibles in landscape designs to reduce food transportation costs
- Use of native plants in the planting design. If selected with the soil, moisture, climate, and exposure conditions in mind, native plants will generally perform better and require less maintenance and thus fewer energy inputs than fussy exotics.
- Eliminating tilling in order to preserve carbon sequestered in soil. Tilling, by increasing the amount of oxygen in the soil, speeds the oxidation of organic matter, releasing CO₂ into the atmosphere.
- Designing site plantings to improve the heating and cooling efficiency of structures and outdoor recreational spaces

Allowed

- When necessary, operating fuel-powered vehicles and power equipment (mowers, leaf blowers etc.) that meet current efficiency and pollution standards
- Using biodegradable fuels and maintenance products whenever fuel-powered equipment is necessary
- Using exotic plants for their carbon sequestration potential, as long as they aren't prohibited in other sections of these Standards
- Plant or maintain lawns in landscapes where attention has been given to other landscape ecology functions
- Use materials from outside the immediate local area, if necessary, to establish a new garden on a difficult site or rehabilitate a degraded landscape before transitioning to a management regime based on local materials

Prohibited

- Clear cutting
- Synthetic fertilizers and pesticides
- Buying materials, including fertilizers and soil amendments, without first checking to see if there is a closer source at little or no additional expense for the same material
- Idling vehicles and equipment
- Spilling fuel into ground, storm drains, and water sources
- Dumping toxic waste into sites other than those designated as appropriate
- Retrofitting fuel-powered equipment with parts that do not meet current efficiency and pollution standards

FERTILIZERS

Fertilizers are tools that enable us to modify existing soil conditions. Fertilizer is not plant food, it is a catalyst that stimulates the plant and soil. In organic land care, we use **organic fertilizers** to feed the soil and the soil, in turn, feeds the plant. This is known as the “feed the soil” principle which is used to benefit plant health, not artificially stimulate plant growth. It is important to understand that this function is reliant upon an active soil organisms which is temperature dependent. The “feed the soil” principle will not work in cold temperatures.

Typically speaking, fertilizers consist of N-P-K (nitrogen-phosphorous-potassium.) N-P-K are the three major (macro) nutrients which plants require in the largest amount to grow. In organic land care, the focus of nutrient goes beyond N-P-K. Most organic fertilizer sources are plant or animal based. Some examples of plant-based fertilizers are soy, corn, alfalfa. Some examples of animal-based fertilizers are feather meal, fish, poultry, blood and bone meals.

Fertilizers are important when beginning an organic land management program. Many times a soil is lacking in its ability to biologically cycle nutrients and requires additional input of N-P-K. In a productive soil, the biomass will break down organic materials, including fertilizers, making nutrients available to plants. The goal over time is to make use of nutrition within the soil organisms, thereby allowing us to reduce fertilizer inputs.

Good stewardship of the environment requires that soil chemistry and (optionally) biological tests be performed before applying additional fertilizers. If the land care professional determines, on the basis of the test results, that a soil requires fertilizer, it is preferred to use renewable materials that are locally and sustainably produced.

Synthetic fertilizers are mostly water-soluble and work quickly when moisture is added. Synthetic fertilizers are a stressful way to fertilize. They are generally salt-based, which may:

1. diminish the functionality of soil organisms
2. affect the soil organisms' ability to cycle nutrients
3. lowers soil's pH, which in turn makes nutrients unavailable to plants
4. lead to the use of synthetic control products
5. create a plant's dependency upon regular applications of synthetic fertilizers

Nitrogen

Nitrogen is an essential plant nutrient because it is required to create amino acids and proteins, genetic material, chlorophyll, and other important biochemical molecules. Nitrogen is the most abundant gas in the atmosphere (78%), but the gaseous form (N_2) is inert and unavailable for use by animals and most plants. Turning N_2 into available nitrogen, or “fixing” it, requires breaking the bond between the nitrogen atoms, which requires energy. Under natural conditions, nitrogen is fixed by lightning strikes through the atmosphere and by the work of a few species of symbiotic bacteria and some free-living bacteria and fungi in the soil or water. The amount of new, naturally “fixed” nitrogen being produced at any time is quite small compared to the amount already fixed and cycling through an ecosystem.

Human activities have almost doubled the amount of fixed nitrogen entering the global cycle through the industrial production of fertilizer, selective cultivation of nitrogen-fixing plants, and the burning of fossil fuels. (See “Human Alteration of the Global Nitrogen Cycle: Causes and Consequences” at <http://cfpub.epa.gov/watertrain/pdf/issue1.pdf>)

These activities have affected natural systems by increasing greenhouse gases in the atmosphere, depleting the ozone layer, increasing acid rain, creating smog, and changing ecosystem balances by favoring nitrogen-tolerant plants over other species while creating deficiencies in other nutrients (calcium, potassium, and magnesium). Nitrates in drinking water have also been linked to human health problems.

Plant and animal nitrogen sources also contain phosphorus; therefore, their use should be limited by the requirements for phosphorus as determined by a soil test.

Phosphorus

Phosphorus, in the form of phosphate, is an essential nutrient for every living organism. It enters soils in natural systems by rock weathering. Leaching and runoff remove it from soils and carry it through aquatic systems to lakes and oceans, where it settles into deep water sediments. These large “sinks” of phosphorus can only be returned to the phosphorus cycle by upwelling of deep waters or geological uplift of marine sedimentary rocks.

Because of the length of time involved in cycling phosphorus out of “sinks,” phosphorus is, for all practical purposes, a nonrenewable resource. Humans get phosphorus from very limited sources around the world by mining phosphorus rock and guano (excrement of bats, birds, and seals). Most of this phosphorus is turned into fertilizers and applied to soils, and a great deal of it then leaches into aquatic ecosystems. In ponds and lakes, excess phosphorus can substantially increase plant productivity and lead to eutrophic conditions, causing increased phytoplankton and bacteria growth, loss of dissolved oxygen, and loss of animal life, especially in lakes.

Recent studies have indicated that global supplies of phosphorus are running low, and remaining supplies are high in the toxic element cadmium. Current estimates are that world production of phosphorus will peak around the year 2030, and that phosphorus will become increasingly expensive and difficult to obtain after the peak. There is no substitute for phosphorus in modern agriculture, and even organic agriculture uses rock phosphate, greensand, and other mined phosphorus fertilizers. It is essential to avoid wasting phosphorus by over-applying it to soil, and it is important to retain phosphorus by composting plant and animal materials and using the compost on site. Efficient use and cycling will also reduce eutrophication of lakes from excess phosphorus.

If a standard soil test gives a rating of medium or above for phosphorus, then no additional phosphorus should be applied. In many states, adding phosphorus without a soil test that indicates a deficiency is prohibited by state law.

Potassium

Potassium is the third element for plant growth. It is a regular component of organic fertilizers. It influences the plants ability to become as stress resistant as possible. It is expressed as potash in a fertilizer analysis. Its primary benefit is the ability to thicken cell walls and impart a degree of stress resistance to the plant. Potassium is relatively soluble in soil solution, but strongly held by clay particles in the soil. Potassium is typically 2-7% of the base saturation of the soils.

Potassium can be found in the soil in the forms of: exchangeable potassium (K⁺ adsorbed on CEC sites), it can be fixed by certain minerals from which it is released very slowly in an available form, and it is found in

unavailable mineral forms. Plants take up potassium as the K⁺ ion.

Unintended Consequences of Fertilizer Applications

Synthetic, water-soluble fertilizers often move off target depending upon soil-type and environmental conditions. Much of the nutrient is not used in its entirety by the plant. This can lead to contamination of fresh water bodies, surface and ground water which includes drinking water, wells , reservoirs and aquifers, and the ocean.

- Drinking water is contaminated by nitrates
- Fresh water is contaminated by phosphorous which leads to algae blooms and hypoxia
- Ocean water is contaminated by nitrogen which leads to algae blooms and hypoxia

Organic fertilizers can have similar unintended consequences if used improperly. Just because a product is natural or organic, does not mean it can be over-applied or applied at inappropriate times. In sandy soils with high leaching rates, particularly those along or near the ocean, the allowable amounts of WIN nitrogen should be decreased to reduce the potential for contamination of down-slope water bodies.

Unnecessary applications of any fertilizer—including those listed as Preferred or Allowed in these Standards—can cause nutrients to build up to excessive levels in the soil. At such levels, nutrients may enter local water resources. Nitrogen and phosphorus are the nutrients most involved in eutrophication of water bodies (nitrogen in oceans, phosphorus in lakes and ponds), and are thus of major concern as pollutants. Nitrogen can also be a hazard to human health when it pollutes drinking water supplies.

Preferred

- OMRI certified products (Organic Materials Review Institute)
- Baystate Organic Certifiers maintains a list of products in the Northeast that have been carefully reviewed and found to be consistent with these Standards. To submit a product for review, please contact Baystate directly at www.baystateorganic.org.
- The least processed forms of fertilizers produced which are manufactured locally

- Fertilizers with non - genetically engineered components or ingredients (GEO)
- Water Insoluble Nitrogen (WIN)
- Cover crops and green manures
- Minimizing the need for nitrogen in lawns by leaving grass clippings, planting low-maintenance varieties, and including legumes in the lawn mix
- Animal or plant based fertilizers
- Naturally occurring forms of phosphorous, not mined forms
- Sulfate of potash (potassium sulfate)

present, the fertilizer is prohibited for use in organic land care.

- Bio-solids (sewage sludge)
- Milorganite-brand or others made with bio-solids
- Applying more nitrogen than is needed based on soil testing. Nitrogen applications that exceed the genetic requirement of the plant.
- Natural sodium nitrate, also known as Chilean nitrate. This is a place where these Standards differ from those of the National Organic Program.
- Application of nitrogen fertilizer to lawns when grass is not growing actively enough to use it rapidly, generally between November 1 and April 1 in Connecticut and Massachusetts or when soil temperatures drop between 50 degrees fahrenheit.
- Allowing fertilizers to remain on sidewalks or pavement (typically after being applied by a rotary spreader). Fertilizers left on pavement wash into storm sewers and then into waterways. Any spillage must be swept up or vacuumed and reused.

Allowed

- Organic fertilizers with ingredients that meet the NOFA Standards for Organic Land Care.
- The least processed forms of fertilizers
- Fertilizers that may contain genetically- engineered ingredients, when it is cost prohibitive to source non-GE comparable fertilizers.
- Mined phosphorous, soft rock phosphate or black rock phosphate
- 1 pound of WIN (Water Insoluble Nitrogen) per 1,000 square feet per application, with a maximum of 3 pounds of WIN per 1,000 square feet per year. Rates of nitrogen application should be further reduced after 2 years of organic management. This guidance is applicable for turf. Landscape beds and trees require less WIN.

Prohibited

- Synthetic fertilizers
- Blended fertilizers containing any prohibited materials, including “transitional” or “bridge” products
- Exceeding the amounts of phosphorus, potassium and other mineral nutrients recommended by a soil test
- Synthetically derived fertilizers. *Note:* Bridge products, blended products or transitional products may contain a mixture of organic and synthetic materials. If synthetic materials or bio-solids are

Caution Statement:

Some preferred and allowed fertilizers may contain contaminants or GE materials. See page 28 for greater detail.

Soil Minerals

The availability of mineral elements depends on environmental factors specific to each site. Good stewardship of the environment requires that soil tests be performed to obtain an accurate picture of the soil chemistry on a particular property. A bioassay provides valuable information about the living components of the soil. If the land care professional determines, on the basis of the test results, that a soil requires amendment, it is preferred to use renewable materials that are locally and sustainably produced. Many mineral nutrients are mined or harvested from natural sources that are not renewable and transported over long distances. We do not want to deplete these resources for our short-term benefit.

All minerals are salts, therefore can be detrimental to the soil microorganisms. Use caution when applying these minerals.

Calcium

Allowed

- Calcitic limestone (calcium carbonate)
- Agricultural gypsum (calcium sulfate) - influences calcium with no pH change.
- Dolomitic limestone - Only could be used when Magnesium is low per soil test.
- Soluble sources of calcium are allowed but does not create a long term pH adjustment

Prohibited

- Burned or quick lime (calcium oxide)
- Hydrated or slaked lime
- Synthetically derived calcium

Sulfur

Allowed

- Sulfur (elemental)
- Epsom salt (magnesium sulfate)
- Agricultural gypsum (calcium sulfate)
- Sulfate of potash (potassium sulfate)
- Sulfate of potash, magnesium (such as Sul-Po-Mag®)

Prohibited

- Synthetically derived sulfates
- Ironite® (contains high levels of lead and arsenic)

Magnesium

Allowed

- Dolomitic limestone - also contains calcium
- Epsom salt (magnesium sulfate)
- Sulfate of potash, magnesium (such as Sul-Po-Mag®)

Prohibited

- Burned or quick lime (magnesium oxide)
- Synthetically derived magnesium

Micronutrient Sources

Nutrients which are required in trace amounts. Micronutrients are insoluble and need to be solubalized to be taken up by the plant. It is important to manage soil biology to release micronutrients already present

(e.g., manganese, zinc, boron, copper, iron, molybdenum, chlorine.)

Preferred

- Proper management of the soil microbes

Allowed

- Rock powders
- Sea minerals
- Kelp and seaweeds
- Fish hydrolysate, emulsion, or meal. Caution: May contain mercury, PCBs, or other contaminants. Be aware when choosing to use fish products that massive over-fishing is causing severe ecological damage in oceans. In addition, farm raised fish may contain antibiotics or genetically engineered fish.

Prohibited

- Synthetically derived micronutrients
- Copper sulfate
- Iron chloride
- Chelated iron
- Ironite® (contains high levels of lead and arsenic)

Materials Used to Adjust pH

Many of these materials are high in salts and produce relatively short term results. They do not change the pH permanently or long-term. The only way to make a long term change would be to buffer the soil pH by influencing the biology.

Preferred

- Compost Tea
- Leaf mold

Note: These organic materials will have a moderating effect on soil pH, but only over time and multiple applications. Inorganic materials such as limestone and wood ashes will elevate soil pH much more rapidly.

Soluble sources of calcium are allowed but does not create a long term pH adjustment

Allowed

- Aragonite
- Calcitic limestone (calcium carbonate)
- Compost
- Dolomitic limestone
- Wood ash
- Granulated sulfur (decreases pH)

Prohibited

- Aluminum sulfate
- Synthetically derived products
- Iron Sulfate
- Ironite® (contains high levels of lead and arsenic)

Other Mineral Supplements - They contain many different minerals and there is little research to define quantities of such minerals.

- Greensand
- Azomite®
- Aragonite
- Kelp meal
- Humates

SOIL AND PLANT AMENDMENTS

Amendments are used to change the physical, chemical, and biological properties of existing soil to improve soil health and quality.

Preferred

- Composts and compost teas
- Cover crops and green manures
- Leaf mold
- Grass clippings
- Ramial woodchip mulch (using branches under 2 inch caliper)

Allowed

- Biochar made from plant residues. *Note:* There are many different materials and techniques used to make biochar, and thus characteristics and behavior of biochar vary widely.
- Humates
- Mulches
- Sugar sources (molasses, glucose, sucrose, dextrose and fruit juices)
- Peat moss as a component of potting soils. *Note:* Although peat moss is widely used as a soil amendment, we do not recommend it because the harvesting of peat moss destroys increasingly rare bog habitats. There are available substitutes such as coconut coir, rice hulls or chaff of any threshed grains.

Prohibited

- Peat moss used to amend landscape soil
- Synthetically derived products
- Anything containing sludge or biosolids

Microorganisms and Inoculants

Preferred

- Compost tea and compost extracts
- Non-GMO (genetically modified organism) microbial inoculants
- Mycorrhizal fungi

Allowed

- Biodynamic preparations
- Soil biostimulants. *Caution:* Beware of false claims and synthetic ingredients.
- Wood ash. *Caution:* High salt and potash content.

Prohibited

- GMO (genetically modified organism) microbial inoculants
- Applying wood ashes from the combustion of painted or treated wood, wood composites, coal, household trash, or glossy (colored) paper

Potting Mixes

Preferred

- Compost- or soil-based potting mixes free of prohibited substances

Allowed

- Compost-free mixes that do not contain prohibited substances
- Yucca extracts used as wetting agents Addition of beneficial fungi and/or bacteria to the mix

Prohibited

- Synthetically derived products
- Synthetic rooting or wetting agents

COMPOST AND COMPOST TEAS

Compost has many advantages over topsoil or mulch alone. It improves soil structure, reduces runoff and compaction, enhances biodiversity, increases water and nutrient retention, increases microbial activity, supplies nutrients, increases root growth, helps prevent and suppress plant diseases, detoxifies certain pesticides, and inactivates or kills potential human pathogens. Compost also provides habitat (and improves the current habitat) for beneficial microbes. This additional and improved habitat will allow for proliferation of beneficial microbes. Additional benefits for the land care professional include: improved establishment of turf, ornamentals, and shade trees; improved foliage color; improved plant performance in marginal or poor soils; and reduced and often eliminated need for fertilizers, pesticides, and irrigation.

Composting is the managed, rapid decomposition and stabilization of raw, clean organic waste to a humus-like finished product. High-quality compost is well decomposed and is highly aerobic due to regular aeration. It is high in beneficial soil organisms such as actinobacteria, fungi, nitrogen-fixing bacteria, aerobic bacteria, and many others. On the other hand, it generally contains low and variable amounts of nutrients. Organic fertilizers may be required to meet some plant nutrient requirements.

A commonly accepted recipe for compost is to use 3 parts by volume carbon-rich brown material (such as wood chips, sawdust, leaves, or shredded paper) and 1 part nitrogen-rich green material (such as grass clippings, kitchen waste, green plant material, or manure). Recipes for compost should ideally be customized based on the end use of the compost and what resources are available locally. For more on compost making, see the Bibliography, page 58.

Characteristics of Well-Decomposed or Finished Compost

Appearance

- Few recognizable components of the initial raw materials
- Color should resemble a brown coco color. (A very dark black compost would indicate that the compost got too hot too quick. This occurs when compost is cooked to extreme temperatures, most of the

beneficial microorganisms are killed off, and the pH is usually very low.)

- Structure is light and crumbly
- Finished compost does not release steam when disturbed

Odor

An “earthy aroma” with no offensive odors such as ethanol, ammonia, or sulfur.

Temperature

Not hot to the touch, or at ambient temperature. While microbes are reproducing intensively, they will generate heat. When the microbial population has decomposed the majority of the compost feedstocks and 90% or more of the microbes have gone dormant, the compost is considered mature. The NOP requirement requires a minimum core temperature of 131 degrees F for 3 days. All quadrants of a windrow need to be turned to the center of the pile and heated to a minimum of 131 degrees F.

Weed seeds

Proper composting at recommended temperatures kills most weed seeds, but a few may survive. A few weeds may appear on a compost pile, without causing worry.

Moisture content

Between 30% and 50% is desired. Above 60%, compost tends to clump and not spread evenly, is heavy and difficult to handle, and can be anaerobic. Below 20%, it produces excessive dust, will tend to wash away, and favors excessive growth of actinobacteria. Proper moisture content is achieved when a hand full of compost can be squeezed and a few drops of liquid is released.

Carbon-to-nitrogen (C:N) ratio

Approximately 15:1

pH

Finished compost has a pH of between 6 and 7 (typically around 6.8), a range that is favorable for most plants, except for most broad-leafed evergreens and some berries. Caution: Adding compost may create extremes in pH which result in reduced availability of some plant nutrients and/or toxicity problems.

Additional methods of evaluating compost quality

1. Laboratory testing which tests the biology, chemistry and maturity is important to evaluating compost. Chemistry testing should include testing the electrical conductivity (soluble salts) of the compost. If soluble salts are too high the compost can have the same effect as fertilizer burn.
2. Commercial composters should have state certification or a permit, as appropriate.
3. Hand held test such as Solvita™ or Cornell pH test
4. A simple test to determine if compost is mature is to put 3 cups of compost in a sealed plastic bag and let it sit overnight at room temperature. If the bag expands, the compost is not finished.
5. Another test is to use the compost to germinate watercress (*Nasturtium officinale*) seeds. If the seeds fail to germinate, or the seedlings are weak, spindly, or distorted, then the compost is not finished. (Note that watercress is listed as potentially invasive and should not be planted in the field.) Garden cress (*Lepidium sativum*) is also a good indicator plant for compost maturity. Red clover (*Trifolium pratense*) is the best indicator of herbicide contamination.

Caution:

Organic matter that is composted improperly may go anaerobic (become putrefied). The most common indication of anaerobic decomposition is offensive odors from the production of ethanol, ammonia, or hydrogen sulfides. Check with your compost supplier for evidence of proper quality control to avoid this problem. *Note:* Under specific conditions, anaerobic compost may be used to create proper growing media for wetland plants.

Caution:

Herbicide Contamination of Compost

In the past, organic farmers and land care professionals have not had to be too concerned about herbicide residues in compost because most herbicides break down rapidly in the composting process. However, certain herbicides like clopyralid, picloram and Imprelis(TM), which break down very slowly in composting, have been found to contaminate compost to the point where sensitive plants are damaged. As a result of these problems, these herbicides may not be registered for residential use, but may be registered for use on commercial lawns and golf courses. These herbicides and similar compounds also continue to be used agriculturally and may be applied

to cereals, hay fields, and pastures. They pass quickly through grazing animals, so compost made from feed stocks, including animal bedding and waste, may also be contaminated. Be aware of these hazards, discuss them with your compost suppliers, and ask them if they have conducted bioassays on any potentially contaminated materials. For more information, see articles on the website of the U.S. Composting Council including <http://compostingcouncil.org/persistent-herbicide-faq>.

Analytical techniques associated with herbicide and pesticide residues continue to evolve, as does our understanding of their degradation pathways. Once in the environment, herbicides are chemically and/or biologically transformed into new chemical entities that no longer kill weeds. However, these breakdown products should not automatically be considered biologically benign. 2,4-dichloro-phenoxyacetic acid (2,4-D) cleaves to produce 2,4-dichlorophenol as its initial degradation product; this halogenated aromatic compound is significantly more toxic than the parent herbicide. When in doubt about including potentially contaminated raw materials into a mix for composting, consider not only the actual herbicide, but also its known or potential degradation products as well.

Preferred

- Composting yard waste properly on site and using the compost in beds or gardens. Locate compost piles away from rivers, streams, and other bodies of water to prevent the runoff of nutrients seeping from the piles. Planted bioswales should be used if needed to sequester excess nutrients and further prevent runoff or leaching. Plant materials from the swales can be harvested and used in future compost piles.
- Compost piles should be covered once they are at desired levels of moisture content. The covers prevent the compost from drying out during warmer periods and prevent the compost from becoming saturated, and thus anaerobic, during rainy periods.
- Using compost made locally from local materials to reduce transport of bulk materials.
- Using compost that is well decomposed for general soil applications. Compost used for compost tea brewing can have some undigested or chunky pieces, which may aid in extraction.
- Monitoring phosphorus levels with soil tests to prevent the build up of excess phosphorus due to

repeated compost applications over time. See state statutes for phosphorous applications.

- Incorporating compost into the soil prior to planting, where soil amendment is needed. Compost may be applied to the soil surface as a 1–2 inch layer (approximately 3–6 cubic yards per 1,000 square feet), then incorporated to a depth of 4–6 inches. A 2-inch layer is appropriate for very sandy soils or soils that are low in organic matter. For more fertile soils, use less. Make sure compost is thoroughly mixed with the soil.
- Top dressing/surface application, as follows:
 - o On turf: ¼ inch or less, no more than two times per year, for no more than three years, unless a soil test shows organic matter remains below 4% and phosphorus is below “medium”
 - o Around perennials: 2 inches or less
 - o Around shrubs and shade trees: 3 inches or less
- Radial trenching or vertical mulching to alleviate compaction around woody plants. Mix equal parts of compost and excavated soil to backfill the trench.

Allowed

- Any compost that appears to be adequately decomposed; does not contain sewage sludge, industrial toxic wastes, large stones, trash, or other prohibited materials; and is made from at least two different raw materials
- Sheet composting (surface application of organic material to compost in place) to establish gardens and beds. Note restrictions under Prohibited, below, on sheet composting of manure where human food crops will be grown.
- Anaerobic compost for growing wetland plants or restoring wetland soils

Prohibited

- Sewage sludge (biosolids), municipal solid waste, and paper mill by-products as raw materials of compost. Current EPA standards are not adequate to protect the public from contamination of biosolids from toxic elements, industrial toxins, pharmaceuticals, and radioactive materials.
- Compost containing excessive amounts of plastic, undesirable objects, or offensive odors
- Compost containing large amounts of viable weed seed

- Planting human food crops within 120 days of harvest in sheet composting systems that use animal manure.
- Using more than the amounts specified under Preferred, above
- Over-application of compost. Repeated applications over time may exceed the limits on nitrogen and phosphorus in the soil.
- Anaerobic compost as a soil amendment

Compost Tea

Compost tea is attracting increasing attention as an inoculant to enhance or restore soil and leaf surface microflora. There is some research to show that compost tea has a role in deterring disease, although the results are highly variable. Recent research conducted by Dr. Clive Edwards of Ohio State University has shown strong and consistent effects of worm compost and tea made from worm compost on plant resistance to insects, mites, and plant pathogens in laboratory studies. Under current laws, however, it cannot be claimed that compost tea suppresses or controls diseases or pests because it is not registered as a pesticide by the U.S. Environmental Protection Agency.

Although compost tea is sometimes made by simply fermenting compost in water, it is now more commonly made in a brewer or extractor, which creates aerobic conditions to yield great quantities of bacteria, yeasts, and fungi in ratios designed for very specific purposes and soil conditions. The extraction and proliferation of beneficial soil protozoa and the extraction of nematodes from the compost are also delivered in the actively aerated compost tea (AACT) or liquid compost extract (LCE.) A range of organic adjuvants, including worm castings, kelp, and/or fish hydrolysate may be added as food sources, and yucca extract, saponin, rock dust, humic acid, and fulvic acid, alone or in combination, may be added to create teas for specific uses. Compost teas may be made through aerobic or anaerobic processes, using different methods designed to produce various results. References to reviews of both aerated and non-aerated compost teas and their effects on plant disease are provided in the Bibliography, page 58.

Research has indicated that aerated teas and extracts are preferred over non-aerated teas because *Escherichia coli* and other human pathogens proliferate under anaerobic conditions.

Definitions:

Actively aerated compost tea (AACT) is a liquid made by brewing and or aerating compost (or worm castings) in water, in order to extract beneficial organisms (bacteria, fungi, protozoa and nematodes). During the brewing process, these organisms are “fed” nutrients to rapidly increase their numbers and activity. It is then applied to soil, roots and leaves of plants. The process of brewing can occur over a period of 12- 24 hours and or sometimes up to 38 hours depending on the recipe, water temperature and type of brewer that is being used.

Liquid Compost Extract (LCE) is different from brewing. Instead of feeding the microbes, the goal is to extract the microbes directly from the compost or worm castings using compost extraction. Since no foods are fed to the microbes during extraction, there is a minimal amount of additional microbial growth. LCE takes very little time to make.

Qualities:

- AACT has a much shorter shelf life after it has been removed from the brewing processes (3-6 hours) depending on temperatures, recipe used and equipment.
- AACT can have a very short shelf life because the brewing processes have increased microbial communities by the 100's and or millions, which normally does not occur in nature. When the aeration is stopped, the microbes will continue to consume all of the available oxygen and foods and depending on the temperatures the liquid will eventually start to go anaerobic which can cause damage to your plants.
- You don't need to apply an AACT to soil -- the organisms will awaken, and begin to grow faster if they are applied to the soil and find places with food, moisture, and air.
- LCE can be made on-demand anytime, so you are not limited by time and volume like you are with AACT.
- LCE can also have a much longer shelf life than AACT and can be kept longer or stable depending on the equipment used to store and apply the LCE.
- LCE can be applied directly to the soil.

Application:

There is research demonstrating that LCE as a drench to the soil is as good as AACT in terms of their ability to improve plant growth, health and soil fertility. However, AACT as a foliar application tends to “stick” better than extract because the microbes are metabolically active and growing when fed over a period of time. Some microbes will produce substances when they are growing which allows them to stick to plant surfaces. With LCE, the microbes are not fed additional amounts of foods and are much less metabolically active and may be still be dormant which is why LCE is used more as a drench to the soil. AACT as a foliar spray does a better job of coating the whole plant with active beneficial microbes. It is this coating that protects the plants from pests and diseases, according to many practitioners, however unsubstantiated by current research as of yet.

According to Soil Foodweb, Inc., perennials, annuals, and turf require a compost tea made from compost in which fungi and bacteria are balanced, or that is slightly higher in bacteria. Compost of this sort can be created by starting with a mixture of 25% animal manure or worm castings, 50% green material (household waste, leaves, and grass clippings), and 25% woody materials (wood chips, bark, sawdust, and mushroom substrates). For shade trees and shrubs, Soil Foodweb, Inc. recommends a compost tea made from compost that is high in fungi. A fungi-dominated compost can be created with an initial mixture of 50% green material, 45% woody materials resistant to rapid decay, and 5% manure or worm castings.

Caution:

There are a lot of variables involved in creating high-quality compost tea. It is therefore important to understand the process thoroughly before attempting to make or use compost tea. There have been reports of *Escherichia coli* and other potential human pathogens multiplying in compost tea, particularly when very high levels of soluble bacterial food resources are used. If very high levels of bacterial foods create a condition where bacterial proliferation is so great that the oxygen demand is higher than the oxygen output of the brewer, the tea may go anaerobic. It is very important to prevent any possible contamination of compost tea with human pathogens and to prevent the proliferation of human pathogens in the tea. Maintaining highly aerobic conditions in the brewer at all times will prevent the proliferation of pathogens.

In addition, it is extremely important that you clean and sanitize your equipment that is used for making and

spraying compost extract and compost teas. Biofilm can be very toxic over time in brewers and sprayers.

Preferred

- Constituent materials preferred by these Standards
- Using AACT aerated compost tea within 6 hours of brewing. LCE Extracted tea can be used for a longer period.
- Using compost tea that contains less than 120 colony-forming units of *Escherichia coli* per 100 milliliters
- Brewing compost tea in which the biology has been adjusted for a specific use. An example would be the judicious addition of soluble fungal food resources to tea during the brewing process to select for fungal proliferation over the course of the brew cycle if the tea is intended for use in woody plant soils, which prefer a fungal dominated soil.
- Applying compost tea as a soil drench, root dip, or foliar application to improve the health and vigor of lawns and landscape plants
- The equipment used to decant AACT or LCE from the brewer or extractor should not damage a high percentage of the microbes during the decanting process. The spray equipment used to apply the AACT or LCE also should not damage a high percentage of the microbes during the application process.
- The water source used to brew AACT or extract LCE should be tested to ensure the quality is good and there are not high levels of chlorine, other disinfectants or contaminating materials that could adversely impact the quality of the AACT or LCE. Chlorine, if present in damaging levels, should be degassed from the water prior to use.
- If AACT or LCE are diluted with water for application, the source of water should be tested to ensure the quality is good and there are not high levels of chlorine, other disinfectants or contaminating materials that could adversely impact the quality of the AACT or LCE. Chlorine, if present in damaging levels, should be degassed from the water prior to use.
- Clean all brewing and spraying equipment after use, to prevent biofilm from building up and contaminating future batches.

Allowed

- General purpose compost tea, in which the biology has not been adjusted for a specific use
- At minimum, cleaning or pressure washing brewers and sprayers with fresh clean water

Prohibited

- Compost tea made with materials prohibited by these Standards
- Compost tea with more than 120 colony-forming units of *Escherichia coli* per 100 milliliters
- Using tanks, sprayers and brewers that are not cleaned and sanitized properly
- Using compost tea that has gone anaerobic and/or smells bad
- We do not recommend purchasing compost tea in a closed bottle or jug

LAWNS AND LAWN ALTERNATIVES

Lawn is an area of land covered with closely cropped plants, usually grasses. Most lawn grasses used today in the Northeast are sun-loving, sod-forming, cool-season species of European descent. Their genetic predisposition is to grow tall, produce flowers and seed, and become dormant during the heat and relative dryness of summer. Typical lawn maintenance - namely, continuous mowing close to the ground, which prevents grass plants from flowering and producing seed, and forcing the plants to stay green and growing throughout the warm season by fertilizing and watering them - is contrary to their natural habits. Pushed in this way beyond their genetic limits, grass plants are under constant stress, requiring yet more inputs to keep them healthy.

The energy and resources required to maintain a weed-free, summer-green, grass carpet cause a great deal of collateral environmental damage. The manufacture and use of machinery for installing and maintaining lawns requires huge amounts of energy and creates air, water, soil, and noise pollution. The manufacture, transportation, and application of pesticides and fertilizers demands yet more energy and releases pollutants into the environment at every stage. Because water travels easily over shorn grasses, lawns increase surface-water runoff and subsequent soil erosion. Limiting broad stretches of the cultivated landscape to a handful of grass species and varieties reduces biodiversity. As this partial list makes clear, the ecological sustainability of our national obsession with high-maintenance lawns must be questioned, and their use curtailed.

There are many low-maintenance lawn alternatives. In sunny areas, low-growing native grasses and grass-like species that are drought-tolerant, nutrient efficient, and disease resistant can be used. Incorporating certain leguminous (nitrogen-fixing) broadleaf plants such as clovers and trefoil with these native grasses adds diversity and durability and provides a supply of natural nitrogen to the lawn. For sunny areas that will not be mowed frequently, mixtures of native grasses and/or wildflowers can be planted as a meadow garden. The “no mow” grass mixes, composed of grasses that are naturally compact and require infrequent, if not zero, mowing, are another alternative. In areas of moist or dry shade there are native, low-maintenance grasses and other plants that will thrive where other grasses fail. In areas too shady for any grass to grow, shade-tolerant, low-maintenance perennials, shrubs,

and trees can add beauty and increase the biodiversity of the landscape. Special attention should be given to plants that are native to the region to increase local biodiversity. In marginal areas of the landscape, just allowing the lawn that already exists (free of invasive species) to grow “wild” will provide an economical, ecological, and sustainable alternative to the high-maintenance lawn, and provide food and cover for wildlife.

Principles

- Lawns are good for recreation, athletics, pathways (provided foot traffic is light), and as separations between different land uses. Lawn areas can be visually appealing, but they can also be a high-maintenance component of an organic landscape. Limiting the size of lawns to what is absolutely necessary reduces maintenance costs and is better for the environment.
- Where lawns are necessary or desired, the ecological footprint should be kept as small as possible by choosing grass varieties and cultural methods that reduce the need for irrigation, fertilizer, pesticides (including organic pesticides), and energy-consuming machinery to a minimum. The demands of some specialized situations (high-profile lawns and athletic fields) can be met organically, but may require the use of more inputs and more time than are required in most residential and commercial landscapes.

New Lawn Installation

Proper installation of a new lawn is essential for its long-term beauty and health, and reduces the need for excessive inputs. Soil testing is the first step (see Soil Testing, page 10). Installation of a new lawn is best undertaken in late summer or early fall, and can be accomplished in several ways. One of the key elements of a successful new lawn is properly prepared soil. Choose a soil type that is close to neutral pH and has a balanced fungal to bacterial ratio. After a proper seedbed is prepared (see Planting Bed Preparation, page 43), soil amendments, as specified by the soil test results, are incorporated into the seedbed. Then an appropriate mix of seeds can be sown by hand, or using a spreader or seed driller, or in conjunction with a fiber mulch that is pressurized and sprayed onto the soil (hydroseeding). Care should be taken to identify all

ingredients in a hydroseeding mixture to ensure they are approved for organic use.

Be careful to choose a seed mixture that is adapted to, and tolerant of, the particular growing conditions of the site. There are many insect- and/or disease-resistant, sun- or shade-tolerant species and cultivars to choose from. Endophytically enhanced grass seed protects the grass from surface-feeding insects but should not be used where the grass may be used as food or feed for ruminant animals, as it will sicken them. Always use several different species and cultivars in the mix to enhance diversity and increase the chances of success.

Ensure good seed-to-soil contact by lightly rolling or dragging the seed into the soil. Use a mulch that is as weed-free as possible, such as sterilized straw, to enhance germination and control erosion. The seedbed should be watered frequently but shallowly. The ideal situation is to maintain a “uniformly moist” seedbed during germination and establishment. Watering should increase in duration but decrease in frequency once the root system has become established. After several mowings and in the absence of hot, dry weather, watering should gradually be decreased. Watering should be eliminated when not necessary.

Sodding is a form of lawn establishment that provides instant coverage and looks impressive right away. Unfortunately, most sod is composed of high-maintenance grass species that have been given large amounts of synthetic inputs and water to meet the demand for cheap sod. At least one New England sod grower uses sewage sludge as a growing medium and soil amendment. Sod can be so dependent on synthetic chemicals and devoid of organic matter that it may not have the ability to assimilate organic forms of nutrients. The use of humates, compost, compost teas, fish hydrolysates, carbohydrates, microbial inoculants, biostimulants, root stimulants, and/or soil flocculants is sometimes necessary to detoxify the sod, reestablish the biology in the root zone, and break down the thick thatch layer that is sometimes present. As a result, a sodded lawn often costs several times more and requires greater inputs than a lawn properly installed and maintained from seed.

Lawn Renovation

Lawn renovation is the process of rejuvenating a partially damaged lawn. It is also useful for filling in bare spots. Lawns may require rejuvenation to repair insect, disease,

or drought damage; recover from soil compaction; or improve vigor and appearance. By adding different varieties of grass, we can improve wear tolerance, decrease disease susceptibility, and increase a lawn’s adaptability to its site. All these changes can alter the dominant cultural regime from high maintenance to low maintenance.

The soil should be tested beforehand (see Soil Testing, page 10) to determine the types and quantity of nutrients that are needed (if any) and the soil pH. If thatch is more than ½ inch thick, the lawn can be de-thatched mechanically. If time allows and thatch is not excessive, the lawn can be de-thatched naturally by increasing the number of microorganisms that break down thatch and boosting their vigor by adding carbohydrates such as sugar, molasses, or dextrose via compost and compost tea. Proper pH (in the range of 6.5 to 6.8) is very important to the development of a healthy lawn and to the vitality of these microbes.

If thatch is over 1 inch thick, mechanical removal with a vertical slicing machine (also known as a vertical mower, not a power rake) is necessary. Where thatch is light to moderate, the use of a core-aerating machine may be sufficient. Excessively thick or tough thatch can be reduced by using a core aeration machine in conjunction with a vertical slicing machine. Thatch should be reduced to ⅛ inch-¼ inch before amending the soil or overseeding. The duff material that comes to the surface during de-thatching should be removed and composted, as long as no persistent herbicides have been applied. If persistent herbicides have been applied in the past, compost the duff separately and return it to the lawn. See Herbicide Contamination of Compost, page 28.

Pernicious weeds should be eradicated by hand pulling, smothering, stripping, or the use of organic herbicides (see Lawn Maintenance, below). Bare soil should be lightly cultivated or filled with a compost/topsoil mix prior to seeding. To seed bare spots after corn gluten has been applied, mix grass seed with a 50/50 mix of compost and topsoil and apply at a minimum thickness of 2 inches, then mulch and water.

Renovation is often the first step in converting a conventionally maintained lawn to organic management. It may be three years before a functioning organic turf ecosystem is fully established. Until the process of building up soil organic matter and soil biology and encouraging the grass plants to develop healthy root systems has been completed, lawn or turf may be susceptible to more weed

infestation and insect damage than the client is used to. The land care professional needs to prepare the client for the challenges of the transition period and counsel patience if he or she starts to have second thoughts.

Lawn Maintenance

The ongoing sustainability of a properly installed lawn is dependent upon proper maintenance. For high-maintenance lawns, fertility levels and soil pH should be maintained by the judicious use of soil amendments and fertilizers, as determined by soil testing. The quantity of inputs can be decreased, and the number of nitrogen-fixing bacteria in the soil increased, by returning grass clippings to the lawn, mulching shredded leaves into the lawn in the fall, using nitrogen-fixing plants in the lawn mix, and applying compost that is high in bacteria. (See Compost Tea, page 29, for the recipe for making bacterial compost.)

Mow using a well-maintained mower with a sharp blade. No more than one-third of the grass blade should be removed at one time, and the grass should be allowed to grow to a height of 3 inches or taller. The taller the grass is allowed to grow, the larger and deeper the root systems can grow and the more effective the turf will be in crowding out competition from weeds. The grass clippings should, if at all possible, be left in place. As they decay, they release nutrients back to the soil; over the course of a growing season, the nitrogen contained in the clippings equals one fertilizer application. When there is a history of using persistent herbicides on a lawn, the grass clippings must remain in place or be composted separately and returned to the lawn. The residues of such herbicides do not break down readily in composting and are a hazard to many broad-leaved plants. (See Herbicide Contamination of Compost, page 28, for more information.)

When needed, nutrients can be added to a lawn in several ways: by applying organic matter (typically in the form of compost); by returning grass clippings and shredded autumn leaves to the soil; by using a blended organic fertilizer; by including plants in the lawn that fix nitrogen; or by applying individual nutrients. When applying compost, spread it evenly in a thin layer approximately ¼ inch thick. Compost can be added to a lawn in both spring and early fall.

On healthy, established turf, systematic watering is generally not needed and is not recommended. Water is a

precious resource requiring large amounts of energy and infrastructure to deliver, and must be conserved. Lawns watered regardless of need eventually become dependent on it. If watering an established lawn becomes necessary, it should be watered deeply (to a depth of 6 inches or more) and infrequently. The soil needs to dry out partially between waterings to allow gas exchange between the soil and the atmosphere. Too much water will fill the pore spaces in the soil, suffocating roots and soil life and increasing the likelihood of disease. Watering should be timed and the saturation depth checked to determine how long to water a particular area. Do not water to the point of runoff (see Water Use and Water Quality, page 15).

Proper management of insects and diseases begins with a five-step process that does not include the use of pesticides:

1. Identify the pest
2. Learn about the pest's biology
3. Determine tolerance levels
4. Modify habitat to deter pests
5. Monitor pests

Only if the pest remains above tolerance levels after these five steps have been followed is the application of pesticides to be considered: Pesticides - even organic ones - can kill beneficial life forms. It is very important to accurately identify the pest and know its life cycle and how it damages the grass plant. A healthy soil harbors copious amounts of active microorganisms and humus, which remedy imbalances that can prevent a pest outbreak. Many times a pest is not present in numbers high enough to warrant control. Other times a natural control (a predator, antagonist, etc.) may be present, preventing serious damage without requiring intervention from the land care professional. Do not initiate a pest control measure unless damage exceeds economic and/or esthetic thresholds. Consult cooperative extension publications for thresholds. As a long-term response, cultural methods such as planting resistant cultivars or endophytically enhanced varieties, or improving air circulation should be implemented. If immediate control becomes necessary, use only organically approved pesticides. Before applying a pesticide, read and understand the label instructions and warnings and follow all applicable laws (see Pest and Disease Management, page 50).

Weeds are tolerated in an organic lawn to varying degrees (determined by the client). Many so-called weeds are actually beneficial to the lawn ecosystem. It wasn't until the advent of selective herbicides that a lawn consisted

only of grasses. Before then, a lawn consisted of any and all plants that lived under the mower blade. In most cases it is time to return to that mindset. If weed control is deemed necessary, there are several products on the market approved for organic use. For pre-emergent weed control, corn gluten meal is the material of choice. It is applied in the spring, before weeds emerge, usually between forsythia and lilac bloom. Corn gluten meal is high in protein and thus contains approximately 10% organic nitrogen. This nitrogen needs to be figured into the total allowable amount of nitrogen applied per year (see Nitrogen, page 21). Weeds that already exist in a lawn can be controlled organically through the use of non-selective herbicides made from ethanoic and acetic acids or potassium salts of fatty acids. When using a non-selective herbicide, spot spray weeds, being careful to avoid any unnecessary overspray or drift onto desirable lawn or plants; the overspray will kill or deface any living green tissue on contact. Care should also be taken not to get any spray on the body. As with any pesticide, read and understand the label before use and follow all applicable laws.

Preferred

- Reducing the size of lawn areas to what is absolutely necessary
- Lawn seed mixtures consisting of low-maintenance grasses, broadleaf plants, and/or legume varieties appropriate for the site
- Lawn alternatives, such as “no-mow” lawns, native grasses and wildflowers, native or low-maintenance perennials, herbs, shrubs, and trees
- Allowing lawn to grow unmowed
- Covering high-traffic recreation and pedestrian areas with mulch, sand, etc., instead of turfgrass. *Note:* Recycled rubber tire mulch is prohibited in these Standards, and for playgrounds, there are Child Safety standards and Americans with Disabilities Act standards to consult.
- Disease- and/or insect-resistant grass cultivars
- Mowing to maintain a height of 3 inches or more
- Irrigation by natural rainfall only
- Seeding or overseeding in fall to minimize the amount of water needed for germination and the establishment of young grass plants

- Leaving grass clippings on the lawn
- Returning shredded leaves to the lawn in the fall
- Having soil tested to determine nutritional needs prior to the application of amendments or fertilizers
- Thatch removal using thatch-reducing soil amendments

Allowed

- Mowing at less than 3 inches in height, but not less than 2 inches, except for sports turf
- Irrigation to establish grass (see Water Use and Water Quality, page 15)
- Removing grass clippings and/or leaves, if composted and used on site. If persistent herbicides have been used in the past, compost clippings separately and use resulting compost on the lawn only.
- Blended organic fertilizers, as recommended by soil testing
- Soil conditioners and biostimulants
- Application of minor amounts of organic rock powders that do not contain nitrogen, phosphorus, or potassium, without first testing the soil
- Conventionally grown sod, in conjunction with a detoxifying program
- Mechanical thatch removal when thatch is more than ½ inch thick
- Maintenance of existing lawns, with little or no inputs, in wetlands or riparian areas
- Cultivars bred to remain green under low nitrogen use
- Core aeration when adding soil amendments
- Corn gluten meal. One application per year of 20 pounds per 1,000 square feet. *Note:* This application provides 2 lbs. of nitrogen per 1000 square feet, whereas these Standards allow just 1 lb. of nitrogen per 1000 square feet per application. Extra precautions against run-off are required and additional nitrogen fertilization must be reduced accordingly. See Nitrogen, page 21, for annual nitrogen limits.

- Herbicides allowed under the National Organic Program

Prohibited

- Planting lawn within a wetland or riparian border
- Genetically modified organisms (e.g., Roundup-Ready® grass seed)
- Monoculture stands of a single species of turfgrass
- Cultivars of turfgrass that are known to be disease- and/or insect-prone
- Species and cultivars of turfgrass with high nutrient and watering requirements
- Synthetic pesticides, synthetic fertilizers, and synthetic soil conditioners
- Biosolids (also known as sewage sludge)
- Endophytically enhanced grasses where the grass may be grazed by livestock or wildlife
- Mowing less than 2 inches in height, except for sports turf
- Excessive irrigation, resulting in runoff, compaction, and/or disease
- Installation or use of improperly adjusted irrigation systems (see Water Use and Water Quality, page 15)
- Application of nitrogen, phosphorus, or potassium without soil testing
- Bringing grass clippings from lawns to which persistent herbicides have been applied to composting facilities (see Herbicide Contamination of Compost, page 28)

NATIVE, EXOTIC, AND INVASIVE PLANTS

Native plants evolved in harmony with their environment over the course of millennia. During this evolution, they adapted to their habitat in relation to other species of plants and to insects, animals, and other organisms to create an intricate web of life. The web has woven itself repeatedly over thousands of years in response to disturbance, such as glaciation, and to management by Native Americans.

The colonization of North America has had a profound impact on this web of life. The burgeoning human population and associated development have altered the landscape and reduced natural areas to a handful of fragmented parcels. Meanwhile, humans have introduced, either intentionally or inadvertently, a large variety of exotic plants, some of which have spread rapidly and become pests in natural or minimally managed habitats such as woodlands, grasslands, and sea shores.

Not all non-native plants are invasive. In fact, most are not. Many ornamental plants and the majority of our fruits and vegetables are not native to the United States and are not invasive. The qualities that cause certain plants to be called invasive are defined in different ways. Here are the criteria used by the Connecticut Invasive Plant Working Group:

- The ability to establish new plants and grow rapidly under a wide variety of site conditions
- A high reproductive rate
- The ability to disperse over wide distances, often by the spreading of vegetative fragments as well as seeds
- The lack of the natural controls on growth and reproduction that would be found where the invader is native.

The Massachusetts Invasive Plant Advisory Group defines invasive plants as “non-native species that have spread into native or minimally managed plant systems in Massachusetts, causing economic or environmental harm by developing self-sustaining populations and becoming dominant and/or disruptive to those systems.” Invasive plants may also create significant changes in the composition, structure, and ecology of the natural environment, including changes in soil chemistry, biology, and structure.

In addition to their ability to compete for sunlight, water, and nutrients, invasive plants may have few or no natural enemies to keep their populations in balance with the rest of the local ecosystem. With no check on their growth or spread, invasive plants are able to form monocultures where no other plant grows, disrupting the food chain upon which insects, birds, and other animals depend.

Invasive plants also have a severe economic impact. According to researchers at Cornell University, invasive plants in the United States cause environmental damage amounting to as much as \$120 billion per year.

Regional, state, and federal governments or agencies are now in the process of developing “banned” and “watch” lists. In some states, banned plants may be illegal to move, sell, purchase, transplant, cultivate, or distribute. Invasive plant species lists by state can be found online or from your local horticultural extension office. In states that do not have legislation to ban invasive plants, many invasive species are still commonly available from wholesale and retail nurseries, and invasive species are still being sold via the Internet. Land care professionals need to become familiar with the lists of invasive and potentially invasive plants in their state and be sure that they are not purchasing these plants or installing them in the landscapes that they manage.

Approximately 85 percent of the invasive woody plant species in the United States were introduced for landscape or ornamental use. Studies have shown that it can take up to 20 years from first introduction for a plant to become invasive and begin to cause problems in the natural landscape. Therefore, the precautionary principle should be applied when deciding which plants to use in an organic landscape: A plant whose invasive potential is unknown should not be planted.

The importation of exotic plants poses additional risks. Exotic species of insects, fungi, and other organisms can come along for the ride unnoticed, then attack native plants. Because native plants did not evolve with these pests and pathogens, they often have no defense against them. There are numerous examples of the devastation these stowaways can wreak, including chestnut blight, Dutch elm disease, and hemlock woolly adelgid. It is illegal to import plants into the United States without a permit from the U.S. Department of Agriculture. Land care

professionals should also use caution when purchasing plants from other parts of the United States.

What is Native?

There is a great deal of debate surrounding the definition of “native.” Generally, a plant is considered to be native if it was growing in the area prior to the arrival of Europeans. Beyond that, land care professionals may have to make their own decisions about where they are willing to draw their “native” circle. If the property is located in the western part of Massachusetts, for example, you might consider a plant native if it naturally grows in the Berkshire region, in New England, or anywhere in the Eastern United States. For guidance on this subject, we suggest you seek out an expert. The Northeast, and many other parts of the United States, have native plant organizations that can help landscapers figure out what is native to their local region. The New England Wildflower Society (www.newfs.org) is a good place to start, and their website has a listing of native plant societies in the United States and Canada.

The Cultivar Debate

There is currently a debate among scientists as to whether all cultivars of certain invasive species are themselves invasive. A general definition of “cultivar” is a variety of plant not normally found in wild populations that has been selected for some feature that distinguishes it from the species and that is propagated by horticultural techniques.

Long-term studies are being conducted to determine whether there are any cultivars of invasive species, such as Burning Bush (*Euonymus alata*) and Japanese Barberry (*Berberis thunbergii*), that are barren (unable to produce viable seeds). Research thus far has shown that even cultivars that are currently being marketed as sterile do indeed produce viable seeds. It has yet to be seen whether a truly sterile cultivar can be developed. For this reason, we have decided to prohibit cultivars of invasive species from organic land care.

Principles

- Native plants have special value in the landscape because they help to maintain or restore the original web of life that evolved in a particular place - the animals, microbes, and associated plants that belong to the soils and climate of that site.

- As human beings have traveled the Earth, they have transported many species of plants and other organisms with them, either deliberately or inadvertently. We may choose to use these exotics in our landscapes, but we need to be aware that there is a risk that they may escape from cultivation and crowd out native species or do other harm to the native web of life in ways we cannot foresee.
- Invasive organisms are exotic plants, animals, and microbes that have been shown to spread to natural areas and disrupt the local web of life. We should avoid spreading invasive organisms as part of the general principle, “do no harm.”

Appropriate Plant Choices

Preferred

- Native species, ideally specimens that were organically propagated by a local nursery from plants that were originally found within the local bioregion
- Cultivars of species native to the local bioregion
- Plants that perform multiple functions (food for humans or for wildlife, shade to reduce the need for cooling buildings, wind breaks, etc.)

Allowed

- Plants native to other parts of North America and not known to be invasive in the place where they will be planted
- Non-native, noninvasive plant species appropriate to the ecology and microclimate in which they will be planted

Prohibited

- All plants considered to be invasive or potentially invasive in a given state or region.
- All cultivars derived from species considered to be invasive, including hybrids between invasive and non-invasive species
- Removing, destroying, or collecting seed from native plants in the wild, along the roadside, or on public or private land without prior permission. Rescuing native plants that will be destroyed by development is encouraged, but it is important to get permission from the land owner and local government officials.

Treatment of Existing Invasive Plants

It is strongly recommended that invasive and potentially invasive plants be removed from all sites under management. Land care professionals must first be sure to correctly identify a plant as invasive and then determine the best way to remove and dispose of it. For example, certain invasive plants may be pulled or dug, but extreme care must be exercised to prevent further propagation from root or stem fragments or other propagules. Disturbance of the soil by digging may also bring invasive plant seeds to the surface. Best organic removal methods are still being studied. The land care professional needs to learn about the biology of the invasives he is battling and research control strategies.

When removal of an invasive plant is not possible or the client refuses to allow it, the plant should, if at all feasible, be pruned immediately after the first flowers begin to fade to reduce or prevent the formation of seed. All flower parts should be removed and composted in a manner that will keep the seed from maturing. It is critical to understand the life cycle and seed dispersal mechanism of a species in order to use this method effectively.

After invasive plants are removed, it is important to fill the void with mulch or a cover crop so that seeds brought to the surface during the removal process will be less likely to sprout, and also to replant with native species as soon as possible to prevent re-colonization by invasive plants.

Preferred

- Hand pulling
- Hand-powered mechanical means (e.g., Weed Wrench, a tool designed specifically for removing invasive woody plants)
- Repeatedly cutting down woody plants with hand tools after each flush of growth to draw down root energy reserves, eventually causing death by starvation
- Pouring boiling water directly over roots
- Mowing with a push reel mower
- Smothering with a thick layer (more than 4 inches) of weed-free mulch, paper mulch under a thick layer of organic mulch, or a temporary covering of PVC-free plastic sheeting
- Girdling

- Animal grazing/browsing
- Biological control of invasive plants, using carefully selected natural insect enemies or pathogens
- Covering the soil disturbed in the process of removal to prevent seeds of invasives from germinating
- Protecting surrounding native habitat during invasive removal

Allowed

- Motorized equipment
- Pruning spent flowers to prevent seed formation, if the client won't allow removal of the plant
- Solarization, which involves covering a low-growing invasive plant with clear plastic sheeting. Thanks to the greenhouse effect, the temperature under the plastic rises high enough to "cook" the plants. This technique can also kill beneficial microorganisms in the soil; after the plastic is removed, the area may benefit from applications of compost or compost tea.
- Flame weeders
- Prescribed burning (the land care professional *must* be trained and *must* request approval in advance from the local fire department)
- Organically approved herbicides. *Caution:* Although approved for use in organically managed landscapes, these herbicides are pesticides and must be handled with great care. The applicator must have a pesticide applicator's license and follow all pesticide laws, including all worker protection safety requirements.

Prohibited

- Synthetic herbicides (such as those containing glyphosate, better known under the trade names Roundup and Rodeo)

Preventing the Spread of Invasives

As stewards of the environment, land care professionals must do everything possible to avoid spreading invasive plants. Unfortunately, it is very easy to spread invasives inadvertently. It can also be difficult to identify invasive species, so it is wise to take precautionary measures. There are two common means of spreading invasives unintentionally: on landscaping equipment and by dumping cut materials.

Landscaping equipment, including shovels, lawn mowers, and excavators, all have the potential to spread invasive plants. Seeds, root and stem pieces, and other propagules can all be transported on blades or other equipment parts and in tire grooves. Transporting invasive plants is obviously bad for the environment, but it could also be a liability risk for the land care professional. This is why it is very important to clean equipment thoroughly before leaving a property. If water is used to clean equipment, it is imperative that the washing be done over a permeable managed surface such as a lawn, and not over an impervious surface such as a driveway, where wash water can run off into storm water sewers or local water bodies.

Some states have laws specifying that cut invasive plant material must be kept on site. This is recommended wherever possible. Unfortunately, most compost piles do not get hot enough to kill invasive plants. Because many invasive plants are capable of growing and spreading even after they have been removed from the soil, it is important to kill as much of the plant as possible before composting.

Preferred

- Thoroughly drying roots and other plant parts away from contact with the ground to prevent re-rooting. Plant material killed through desiccation can be composted or disposed of with other brush.

Allowed

- Bagging invasive plant material and delivering it to a trash-burning facility, or a composting facility equipped to handle invasive species, after checking that such disposal is permitted by law
- Covering areas where invasive plants have dropped seed with old natural-fiber rugs or cardboard, followed by 6 inches of wood chips, to prevent germination. These areas should be monitored for signs of shoots pushing up through the mulch.
- In sunny areas, piling plants together and covering them tightly with a dark-colored tarp to heat in the sun. Edges of the pile should be monitored for signs of re-sprouting.

Prohibited

- Leaving invasive plant material where it can take root and re-establish itself
- Dumping invasive plant material or soil contaminated with invasive roots or seeds on another site
- Incomplete containment of invasive plant material during cleanup or transport. Every seed, every piece of stem or rhizome that escapes is another potential infestation.

ORGANIC TREE CARE

Overview

Trees are a critically important part of the environmental community. Because of their size, long life, and positive impact on their environment, they cannot be easily replaced. Therefore, trees should be located where they will thrive for the long-term.

Arborists and other tree care managers have long employed organic concepts in caring for trees. Organic tree care is founded on the principles of organic plant health care. Organic tree care starts with planting quality trees in an environment where they are well-suited and will thrive. Caring for the soil and rooting environment and using sound organic principles are both key components of organic tree care.

In many states, any pruning requires an arborist license certification.

Because of the long lifespan of trees, tree care is a long term, low intensity process. Focusing on proactive, preventative measures to ensure healthy trees stay healthy is more effective than reactionary cures because we have a limited ability to cure.

Preferred

- Plant the right tree in the right place. Make sure that the species which has been selected for a particular spot is appropriate and adapted to the site. Unsuitable trees will have more stress and will be less likely to thrive in an inappropriate site.
- When planting a tree, proper planting practices should be utilized, as outlined elsewhere in the NOFA Organic Standards and in the ISA Best Practices for Planting.
- Pruning to train young trees should be performed to develop strong structure and a pleasing growth form. Pruning to encourage a strong central leader, and well-spaced scaffold branches and eliminate “V” crotches will create a stronger tree as it develops.
- Soil improvement, whether before, during, or after planting, must follow NOFA Standards as outlined elsewhere in the document. These practices include de-compacting and amending soil with compost, application of activated compost teas, and topdressing the root zone of the tree with organic

mulch. Mulching provides a source of organic

matter to the soil, reduces competition with other plants such as turf grass and weeds, conserves soil moisture, and dampens temperature fluctuations in the rooting environment. See page 48 of the NOFA Standards for Organic Land Care for mulching standards.

- When soil fertility needs to be improved, soil testing should always be done to determine the needs of the tree. Organic fertilizers must be used.
- The critical root zone of a tree, defined as the minimum area necessary for the health of the tree, should be protected from compaction and mechanical injury of the roots. (i.e. excluding heavy equipment or vehicles from the critical root zone (CRZ))
- Pruning trees should be done in accordance with ANSI A300 standards. https://www.tcia.org/TCIA/BUSINESS/ANSI_A300_Standards_/TCIA/BUSINESS/A300_Standards/A300_Standards.aspx
 - o Pruning trees should be done at the proper time of year to minimize stress on the tree. The proper timing will vary depending on your geographic region and the species being pruned. Please consult your local cooperative extension, college, or arborist association for best practices.
 - o Proper pruning cuts should always be made. When removing a branch, the branch collar should be left intact to ensure proper compartmentalization and callus formation.
 - o When reduction cuts must be made, the cut should always be made right above a lateral branch to allow the redirection of energy into the lateral. The lateral branch should be at least 1/3 of the diameter of the terminal branch removed.
 - o Large tree pruning is a potentially dangerous activity and should only be undertaken by trained personnel with the proper equipment under the supervision of a qualified arborist.
- If there is a question about the safe condition of a tree, the risk should be assessed by a qualified arborist with risk assessment expertise before any

other treatments are prescribed.

Allowed

- After testing soil to diagnose nutrient deficiencies, amending soils with organic fertilizers is allowed. These fertilizers may be applied as a liquid drench or soil injection, or as a topical granular application.
- The application of organic soil amendments that augment or introduce soil biology, including microbial food sources from organic sources, is allowed.
- De-compaction of compacted soils, using an air tool to loosen soil, is allowed. This can include sheet excavation (and replacement) of compacted soils in the dripline of the tree, radial trenching out from the base of the tree, or vertical mulching, drilling a grid pattern of holes to be filled with organic soil amendments
- Incorporating organic soil amendments that encourage soil biology, including compost, mycorrhizal inoculants, and microbial food sources, is allowed.
- Using an air tool for the incorporation of soil amendments is allowed.
- Pest management treatments deemed necessary in caring for trees should conform with the Pest Management Standards found elsewhere in this document.
- Rescue treatments using non organic pesticides, to control insect and disease problems that can cause significant harm to the tree, are allowed, providing there are no effective organic alternatives. These materials must be applied by properly licensed applicators in accordance with federal and state laws. See page 3 for rules regarding use of Emergency Non-Organic Rescue Treatment.
- Crown restoration pruning, defined by the ANSI Standards as the selective removal of branches, sprouts, and stubs from trees that have been topped, severely headed, vandalized, broken in a storm or otherwise damaged, is allowed when necessary.
- Dynamic or static cabling systems, bracing, guying or supports may be installed to help compensate for structural flaws or weaknesses in a tree, especially where the risk of failure due to such flaws is high.

Prohibited

- Synthetic pesticides, including neonicotinoids, pyrethroids, carbamates, and organophosphates, except when used as an Emergency Non-Organic Rescue Treatment in the manner described above.
- Synthetic insect growth regulators
- Synthetic plant growth regulators
- Synthetic fertilizers
- Damaging root systems or degrading rooting environments, including:
 - o Compacting soils
 - o Changing drainage patterns
 - o Filling or adding soil to the root zone
 - o Contaminating soils
 - o Using soil fumigants
 - o Cutting roots (except for root pruning)
- Improper pruning practices, including
 - o Topping
 - o Flush cuts
 - o Leaving stubs
 - o Inappropriate thinning such as lion-tailing
 - o Excessive foliage removal (more than 25% of the trees foliage at any one time)
- Filling decay cavities

PLANTING

Planting Bed Preparation

Planting beds are prepared differently when an organic approach is used. The well-being of the soil always comes first. The kinds of plants grown, the site conditions, and the desired outcome dictate the method or methods of preparation. If a soil test indicates the need for amendments, they should be incorporated into the soil whenever possible. A soil bioassay may indicate what plants will do well with the existing soil biology or ways to adjust the soil biology to suit the desired plants.

Although many variations exist, there are two basic approaches to preparing the soil in a planting bed. The first is to not amend the native soil at all. This requires great care in selecting plants that match the soil types and site conditions on a property. Foregoing the conventional amendment process requires fewer inputs and is less expensive, but requires more knowledge. The second approach is to amend the existing soil with compost or organically approved minerals and nutrients. This approach may result in more lush growth, and may require additional inputs to maintain that growth. Highly amended soil may be too rich for some plants, making them prone to problems and requiring higher maintenance. Excessive nitrogen and phosphorus may also cause pollution.

Specimen trees and shrubs should generally be planted in soil that has not been amended. The native soil should be loosened well beyond the sides of the root ball but no deeper than the height of the root ball. If amendments are to be used, it is best to amend the surrounding soil as well as the planting area in order to provide sufficient growing area for the roots. Plant roots have a tendency to stay in the richly amended soil rather than spread into the less hospitable surrounding soil, resulting in a constricted root system and loss of vigor due to excessive root competition in a confined area.

In rare circumstances the soil may be so poor or contaminated that the best approach is to replace the soil prior to planting. For soils contaminated with toxic elements, refer to Toxic Elements in Soil on page 11. Contaminated soil must be disposed of in accordance with all state and local laws. Imported soil may contain hazards of its own, such as weed seeds, invasive plant material, and pollutants. Be aware that there is ecological damage created when topsoil is mined.

Whether the soil is amended or not, choosing the right plant for the right place will yield consistently good results and will help to ensure the long-term health and sustainability of any planting.

Preferred

- Preserving desirable existing native vegetation whenever possible
- Choosing plants that match existing site conditions
- Using soil found on site, as available and appropriate
- Manually removing (stripping) unwanted vegetation and roots in areas to be planted
- Composting unwanted vegetation on site
- Smothering unwanted vegetation with old natural-fiber rugs, layers of cardboard, or organic matter
- Using amendments per soil test recommendations
- Incorporating amendments into the soil
- Mulching with organic matter (e.g., shredded leaves or compost - see Mulches on page 48)

Allowed

- Altering site conditions to accommodate a plant's cultural requirements
- Rototilling to remove unwanted vegetation
- Solarizing unwanted vegetation with clear plastic sheeting (plastic should be removed and reused)
- Flame burning or scalding unwanted vegetation
- Herbicides allowed under the National Organic Program
- Composting debris off site
- Using soil imported from off site
- Mulching with bark or inorganic products (see Mulches, page 48)

Prohibited

- Adding nitrogen, phosphorus, or potassium without a soil test

- Leaving amendments on the surface. The nutrients in exposed amendments may be leached away in runoff.
- Disturbing protected areas such as riparian and wetland areas (obey all applicable laws)
- Using soil amendments or fertilizers that are inconsistent with these Standards (see Fertilizers, Page 21, and Soil and Plant Amendments, page 26)
- Synthetic herbicides, fertilizers, wetting agents and water-retaining polymers

Cover Crops, Green Manures, and Crop Rotations

Cover crops and green manures help maintain soil organic matter, add nitrogen, reduce leaching of soluble nutrients, make insoluble nutrients more available to the next crop, prevent erosion, interrupt disease and pest life cycles, and suppress weeds. They are particularly useful in temporarily covering bare soil. When a green manure or cover crop is turned under, its organic matter and nutrients feed the soil biota, which in turn feed the next crop. Although cover crops and green manures cannot be rotated with perennial crops, benefits accrue from cover crops planted prior to perennial crops or between rows or plants.

A few guidelines: Wait one to two weeks after turning under a green manure before planting. This delay allows residues to break down and release their nutrients. If rye or other non-legumes have become too mature before being turned under, they may temporarily bind soil nitrogen and take longer to break down. Nitrogen is wasted when a lush, succulent legume is turned under more than two weeks before planting another crop. Legumes should never be turned under in the fall because they may release soluble nitrogen, which is vulnerable to leaching. Finally, minimize the length of time the soil is bare.

Where a crop of vegetables or annual herbs is removed and not allowed to recycle on site, crop rotation can bolster the health of the soil. Growing the same plants repeatedly on the same piece of ground invites disease and depletion of nutrients in the soil. A crop rotation plan is strongly recommended. When selecting cover crops or green manures, alternate light and heavy feeders, legumes and non-legumes. It is also best to follow a crop with a cover crop or green manure that has different or complementary nutritional needs. Avoid growing two

successive crops that are from the same plant family or are subject to the same pests or diseases.

Seeds, Transplants, and Nursery Stock

Every effort should be made to find sources of organically grown seeds and plants or to produce them oneself. Growers of plants sold as “Certified Organic” should follow the standards issued under the National Organic Program.

Preferred

- Purchasing all shrubs, trees, seedlings, plugs, rootstocks, and other propagative forms of plants from certified organic sources
- Organically grown seeds
- Nontoxic seed treatments such as hot water soaks and legume inoculants

Allowed

- Conventionally grown shrubs, trees, seedlings, plugs, rootstocks, and other propagative forms of plants and untreated seeds
- Pelletization (of seeds) that does not use prohibited materials

Prohibited

- Fungicide-treated seeds
- Genetically modified seeds and plants
- Synthetic rooting or wetting agents
- Planting commercially propagated rare, endangered, or threatened plants (to preserve the genetic integrity of wild populations of these plants)
- Collecting plants or their seeds from the wild, along the roadside, or on public or private land without prior permission. Rescuing native plants that will be destroyed by development is encouraged, but it is important to get permission from the land owner and local government officials.

PRUNING

Our first thought should be to “do no harm.” Organic land care practitioners are expected to care about what they do and possess the knowledge, proper tools, and necessary licenses and/or certifications to do the job. Because plants are living systems, it is important to know how these systems work and how to work within them. Since living systems use gradual processes to grow, our practices should avoid methods that yield quick results or drastic changes. Poor pruning practices can result in a weak, unsightly plant or even cause death. Many of the old pruning practices have been shown to be harmful. Therefore, education in proper pruning methods is very important.

Plants should be encouraged to grow as their genetics dictate, not as we determine. Whenever possible, leave the shaping and shearing to Disney! Leaves are the “food factories” of a plant. All food produced by a plant is manufactured in the leaves. The more leaves, the more potential to make food. The plant knows best how many leaves it needs and in what spatial arrangements. Our job is to disturb this process as little as possible when pruning - especially with older, less vigorous plants.

The optimum time to prune living wood is when the plant’s energy reserves are high. For most plants this is in late winter, before buds begin to swell. Pruning in late fall or early to midwinter can result in dieback and disease or insect problems because the dormant plant cannot seal off the wound created by the pruning cut. If pruning is necessary during the growing season, wait at least two weeks after the leaves have matured to allow the plant to make and store energy. When removing woody tissue, it is important to make a clean, smooth pruning cut in the proper location. The swollen area where a branch is joined to the plant at a crotch is called the branch bark collar. All pruning should be done just outside this collar, leaving a short stub. Do not tip prune or “top” a plant. This practice only leads to disfigurement and weak plants. Much of the plant’s energy for growth is stored in the tips and buds (symplast) and should be preserved as much as possible during pruning. When size reduction is necessary, it is healthier for the plant to remove an entire branch back to the main trunk or leader (drop crotch pruning) than it is to prune back the tips.

In many states (CT included) you must be licensed to prune woody plants for hire.

Preferred

- Removing deadwood, diseased wood, and crossing and intersecting wood as soon as it is noticed
- Pruning living tissue when energy reserves are high
- Corrective pruning for mechanical stability done when plants are young and wood is less than 3 inches in diameter
- Using drop crotch pruning methods
- For size reduction, removing no more than one-third of the branches back to the trunk or main leader over a period of several seasons
- Pruning at the proper time to ensure proper bud formation
- Rejuvenating a multi-stemmed plant by removing one-third of the oldest wood to the ground over a 3-year period
- Disinfecting pruning tools after their use on diseased wood, or removing diseased wood during the dormant season (see Diseases, page 52, for ways of disinfecting tools)
- Disposing of pruning debris by composting on site

Allowed

- Corrective pruning to improve mechanical stability when wood is larger than 3 inches in diameter
- Rejuvenating a multi-stemmed plant by removal of all stems at one time
- Removing pruning debris to an off-site recycling facility
- Shearing

Prohibited

- Any practice that results in, or contributes to, a decline in the health of a desirable plant
- Topping
- Removing excessive symplast tissue (tips and buds)
- Leaving portions of branches during size reduction
- Using tree gaffs (climbing spikes) while pruning, except for emergency rescue

WEEDS

A weed has been defined as a plant out of place, one whose desirable attributes have yet, perhaps, to be discovered. It is important to distinguish between weeds in the yard and invasive plants causing havoc in natural ecosystems (see Native, Exotic, and Invasive Plants, page 37 for information on invasive plants).

The key to weed control is timing. Careful observation of weed populations and weed seedling emergence patterns after disturbance will help the land care professional develop an appropriate weed control program. Staying on top of weed problems through regular monitoring and prompt removal prevents the formation of large weed populations.

Preferred

- Avoiding conditions that favor weeds: compacted soils, overtillage, overwatering, and excessive or ill-timed nitrogen applications
- Adjusting soil chemistry and/or biology to favor desired plants over weeds
- Covering the ground with desired plants that out-compete weeds
- For weeds in beds containing woody and/or perennial plants, hand weeding, spot spraying with organic herbicides, smothering with mulch, or cultivating by hand
- Mulches to suppress weeds (see Mulches, page 48)
- Installing permanent vertical edging or hand edging between lawn and garden to prevent grass from creeping into beds
- Overseeding with cover crops such as annual ryegrass to fill bare spots in lawns, or white clover or buckwheat to cover bare soil in vegetable gardens
- Shallow cultivation to avoid bringing more weed seeds to the surface
- Boiling water poured slowly and directly over weed roots
- Maintaining lawns at a height of 3 inches or more (see Lawn Maintenance, page 34)

Allowed

- Plastic sheeting, including landscape fabric, that does not contain polyvinyl chloride (PVC)
- Paper mulch beneath an organic mulch
- Flame weeders
- Hot water weed burners
- Vinegar or salt, but only in cracks in walkways and terraces
- Corn gluten meal. One application per year of 20 pounds per 1,000 square feet. *Note:* This application provides 2 lbs. of nitrogen per 1000 square feet, whereas these Standards allow just 1 lb. of nitrogen per 1000 square feet per application. Extra precautions against run-off are required and additional nitrogen fertilization must be reduced accordingly. See Nitrogen, page 21, for annual nitrogen limits.
- Herbicides allowed under the National Organic Program
- Mechanical cultivation

Prohibited

- All synthetic herbicides, arsenates, and caustic acids or salts
- Synthetic growth regulators
- Diesel products
- Petroleum distillates
- Micronutrients in toxic quantities
- Synthetic transpiration suppressants

Issue of Special Concern: Poison Ivy

Poison ivy fruit is an important food for birds. For this reason, poison ivy should be left unmolested whenever feasible. The following procedures are suggested for removing it from an area where humans or domestic animals will have contact with it.

Do not burn

Hand pulling:

- Use non-absorbent gloves that completely cover the arm from fingers to shoulder
- Wear rubber boots
- Before handling poison ivy, apply a protective lotion designed to block urushiol. Urushiol is the oil that causes skin irritation.
- For large jobs, don a Tyvek suit and tape the cuffs to your gloves. Dispose of contaminated suit in a plastic bag.
- Gather plants in bags and dispose of entire collection in the trash. Take care to protect anyone who may come in contact with the trash.
- Be sure to dig out the entire root system to prevent resprouting. Repeated weeding may be needed.
- Wash gloves and boots completely with naphtha-based soap or urushiol-removing cleanser before removing them to dry
- If poison ivy comes in contact with your skin, wash within ten minutes with water or a wet wipe, or wash within eight hours with a product that is formulated to remove urushiol. Such products can also be used to help minimize the spread of rashes.

Grazing:

- Sheep and goats will browse poison ivy without harm to themselves. Repeated grazing is necessary to eradicate the plant.

MULCHES

Mulch is a layer of material - either organic or inorganic - applied to the soil surface. The natural state of soils in this bioregion is to be covered with plant material - whether alive, dead, or both. This layer performs many functions that are vital to plant and soil health. Organic mulches mimic this natural cover by adding organic matter, humus, and nutrients to the soil; providing a substrate for beneficial microorganisms; retaining moisture; controlling erosion; moderating soil temperature fluctuations; and helping to suppress weeds. Inorganic mulches are less desirable because they do not contribute to soil or plant health and are usually more ecologically harmful to produce and transport, but they can sometimes be reused and do not need to be replenished as often as organic mulches.

The proper application of mulch is very important. Too much mulch can inhibit the movement of air and moisture into and out of the soil. Mulch piled up against the trunks of plants can cause the bark to rot, leaving the cambium layer under the bark vulnerable to damage. Dormant buds at the base of the trunk can be forced to sprout into surface roots (adventitious roots) that have no alternative but to grow in the mulch layer where there is little or no food or protection. Lastly, rodents can cause serious damage to trunks by tunneling through the mulch and feeding on the bases of plants. This damage is most common in winter.

It is important to note that mulches that are high in carbon, such as undecomposed leaves and fresh wood chips, can also be detrimental to plants. The microbes that break down carbonaceous materials are able to out-compete plants for nitrogen, and when these microbes are active in large numbers they effectively tie up the available nitrogen in the soil. As decomposition slows, the microbes die off and release the nitrogen in their bodies back into the soil, but in the short term, plant growth, especially of seedlings and annual transplants, may be stunted.

Preferred

- Mulching bare ground as soon as possible to prevent the elements from damaging the soil
- Mulching seeded areas to prevent erosion
- Limiting the mulch layer to 3–4 inches around woody plants and keeping the mulch a minimum of 4 inches away from trunks

- Limiting the mulch layer to 2–3 inches around herbaceous plants and keeping the mulch away from their crowns
- Replenishing mulch to maintain but not exceed the above depths
- Applying a winter mulch (e.g., evergreen boughs) after the ground has frozen to ensure that root systems remain dormant through winter
- Anchoring engineered mulch blankets on slopes having a 3 percent grade or greater with pegs and twine, netting, or mats. Check mulch blankets and anchoring devices for prohibited materials before use.
- Covering bare soil with a cover crop (e.g., annual or perennial rye, hairy vetch, winter rye, oats)
- Compost, partially decayed leaves, partially decayed wood chips
- Sawdust (only for acid-loving plants). Like undecomposed leaves and fresh wood chips, sawdust may temporarily tie up soil nitrogen.
- Buffering materials (e.g., compost) to prevent “shocking” of soil microorganisms when using mulch materials that are at the extreme ends of the pH scale
- A layer of composted leaves or compost to prevent bark mulch from coming in contact with the soil

Allowed

- Un-composted leaves
- Bark. *Note:* Bark, especially pine bark, contains high amounts of indigestible fats, waxes, and lignans. Because they are very slow to break down, bark mulches do not feed the soil the way other organic mulches do.
- Buckwheat hulls and cocoa bean hulls
- Newsprint containing black ink only
- Stone and gravel (mined substances)
- Plastic and polyethylene mulches that are free of

PVC

- Weed barrier fabrics, when used beneath washed gravel or stone
- Mulch layer exceeding 4 inches in total depth, when used to smother undesirable or invasive plants
- Corrugated cardboard

Prohibited

- Mulch layers exceeding 4 inches in total depth, except when used to smother undesirable or invasive plants
- Mulch blankets and anchoring materials containing substances prohibited by these Standards (see Materials in Contact with Soil or Plants, page 11)
- Genetically modified cover crop seed
- Newspaper printed with color inks and inserts printed on glossy paper
- Weed-barrier fabrics beneath organic mulch. Soil and organic matter clog the pores of the fabric and prevent air and water from penetrating to the soil below.
- Dyed mulch, which may contain demolition debris contaminated with lead paint, pressure-treated wood, or other toxic substances
- Mulch made from ground-up rubber tires

PEST AND DISEASE MANAGEMENT

The most effective way to prevent and limit pest problems is to grow healthy plants - by putting the right plant in the right place and building healthy soil. Not all pest outbreaks are harmful to the long-term survival or health of a plant. An outbreak can be a temporary phenomenon quickly eliminated by natural enemies or plant defenses without human intervention, and the plants recover. Client education may be needed on this issue.

Pest control requires a pest management plan, which should include regular monitoring of plant health and pest density. (For information on damage thresholds, consult publications from your cooperative extension office or agricultural experiment station.) When selecting a pest control method, it is important to seek the most specific control for the pest in order to avoid harming beneficial organisms.

All laws must be followed in the application of any material used as a pesticide (including biological products and botanical pesticides). State certification as a pesticide applicator is required for any commercial application of pesticides. Check with your state government regarding the need for specific licenses in specific situations.

Commercial application of materials for pest management is illegal unless the materials are registered by the Environmental Protection Agency (except for the 25b materials discussed below) and the state government, and labeled for the plant to be treated and the site. *The label is the law.* Label restrictions on crop or plant species, application rates, and requirements for worker protection must be followed. If you are an employer who uses pesticides of any kind, including organic pesticides, make sure you are in compliance with requirements for worker protection (such as use of protective clothing, reentry intervals, decontamination, and emergency medical assistance). More information on the Worker Protection Standard is available from the U.S. Environmental Protection Agency (EPA) at www.epa.gov/oecaagct/htc.html. In addition, state law may require pesticide application signs and neighbor notification.

An increasing number of pest management products that are classified as “minimum risk pesticides” and are thus exempt from EPA registration have come onto the market in recent years. These are often referred to as “25b” pesticides, after the section of the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) that created

this exemption from Federal registration. The criteria for exemption from registration are that all active and inert ingredients are on the respective EPA lists of materials considered to be non-toxic and that the label meets certain specific requirements. Note that manufacturers of 25b materials are not currently required to demonstrate the efficacy of their materials against pests, so let the buyer beware.

Although 25b pesticides are exempt from Federal registration, state registration may still be required in many states. In addition, the rules for commercial application of these products are the same as those for registered pesticides, and a person who applies them for hire must be a certified applicator. EPA-registered or 25b products labeled for home use may also be used by a professional in a residential setting as long as the label does not specifically prohibit professional use.

You can find out whether a product is registered in your state by contacting the responsible state regulatory official (a list of state pesticide control officials can be found on the Association of American Pest Control Officials website aapco.ceris.purdue.edu/htm/control.htm). An additional source is Kelly Solutions, which keeps a database of registered pesticides for 36 states (www.kellysolutions.com), but the final word always comes from the responsible state official.

Note: Pesticides allowed for use in these Standards are all either EPA-registered or 25b pesticides (exempt from EPA registration) and contain no synthetic inert ingredients unless they are in the 205.601 (m) list of allowed synthetic inerts on the National List of Allowed and Prohibited Substances of the National Organic Program.

Principles

- Insects and other arthropods, fungi, and even snails and slugs are essential to sustaining the web of life on Earth. Human beings choose to protect their plants and other resources from competition or damage from these organisms, and thus consider them to be “pests.”
- The best way to manage pests is to prevent the pests from reaching damaging levels. By using his knowledge of the pest, the plant, and the local ecosystem; of the natural enemies that limit pest populations; and of the biological and cultural

methods that can be used to prevent conditions favorable to disease, the land care professional can foster an ecosystem in which pest outbreaks are uncommon.

- Pesticides, including pesticides allowed in organic land care, should be used only as a last resort, after habitat modification and non-chemical methods have failed.
- If pesticides are to be used, the criteria for choosing the best pesticide option should be:
 1. Minimize known or suspected effects on human health
 2. Minimize known or suspected effects on the environment
 3. Minimize persistence in the environment of the applied material and its breakdown products
 4. Maximize the effectiveness of the material so that the amount and the number of applications can be kept to a minimum. For example, using pesticide in a bait is preferable to broadcasting it into the environment.
- It is an underlying assumption in organic land care that carefully chosen, naturally occurring materials are best able to satisfy the above criteria and are least likely to have unanticipated negative effects in the long run.

Insects and Other Arthropods

Preferred

- Planting species and varieties that are resistant to pests or tolerant of their damage
- Careful inspection of nursery stock to detect and remove any infestation before planting
- Diversifying plant species and varieties to avoid monocultures
- Conservation or improvement of habitat for natural enemies of pests (such as planting flowers that provide pollen and nectar to beneficial insects)
- Making the environment unsuitable for the pest (such as using wood chips as a barrier to the movement of ticks)

- Removal and proper disposal or composting of infested plant parts
- Timely planting of annual plants with attention to pest life cycles

Allowed

- Mechanical measures, such as traps, nets, hand picking, and vacuuming
- Pheromones and other attractants used to monitor or trap pests or disrupt mating
- Releasing predators or parasites such as lacewings (eggs or larvae), parasitic wasps, or insect-attacking nematodes
- Releasing insect or arthropod pathogens such as Milky Spore® bacteria or *Beauveria bassiana*, provided they are not genetically engineered
- Insecticides whose active ingredients are extracted from naturally occurring microbes, such as Bt (*Bacillus thuringiensis*) or spinosad
- Insecticidal soaps. *Note:* Insecticidal soaps can damage some plants. Apply with care.
- Spray oils derived from plant or animal sources
- Narrow-range, or superior, horticultural spray oils derived from petroleum. These oils can be used during both the dormant and growing seasons.
- Botanical insecticides, such as pyrethrum or neem. *Note:* These are broad-spectrum poisons that are hazardous to humans, wildlife, soil organisms, and beneficial insects. They should be used with discretion and not on a regular basis
- Products based on extracts from food-grade materials such as hot peppers or garlic and on plant essential oils, including clove oil (eugenol), floral extracts (2-phenethyl propionate), thyme oil (thymol), rosemary oil, and wintergreen oil
- Boric acid for ant control. *Note:* Boric acid may not be used in direct contact with food crops.
- Diatomaceous earth, if labeled for use in your state. *Caution:* Protection is needed against breathing the dust.
- Elemental sulfur and lime sulfur

- Sucrose octanoate esters
- Common glue (casein) to seal pruned rose canes against borer damage

Prohibited

- Any synthetic insecticide not listed above, including neonicotinoids, synthetic insect growth regulators, pyrethroids, carbamates, organophosphates, and piperonyl butoxide (used as an insecticide synergist)
- All soil fumigants
- Nicotine, nicotine sulfate, and tobacco dust
- Sodium fluoaluminate
- Mothballs
- All other persistent poisons, such as arsenic
- Genetically engineered organisms or materials derived from them
- Any pesticide formulated with inert ingredients that are prohibited under the National Organic Program

Snails & Slugs

In most landscapes, snails and slugs can be tolerated and cause only cosmetic plant damage. When present in large numbers in a bed of newly planted seedlings, however, they can weaken or kill the plants.

Preferred

- Modification of the environment to make the habitat drier and to eliminate protected hiding places
- Planting plants that slugs and snails do not eat
- Copper or zinc strips or mesh used as barriers
- Traps
- Predation by chickens or ducks

Allowed

- Slug baits with ferric (iron) phosphate as the active ingredient
- Diatomaceous earth, if labeled in your state for use against snails and slugs in the landscape. *Caution:* Protection is needed against breathing the dust.
- Barriers of sawdust or wood ash

Prohibited

- Slug or snail bait containing synthetic molluscicides such as metaldehyde

Diseases

Plant pathogens include fungi, bacteria, viruses, nematodes, and phytoplasmas. These organisms can be dispersed by wind and water, insects, mites, and other organisms; by contaminated tools and equipment; and by human activities such as planting, pruning, and cultivating. Pathogens, which are usually present in the environment, often infect stressed or weakened plants. As a consequence, the key to disease management is prevention by maintaining plant and soil health. Client education is another important component of disease management, since not all plant diseases require or warrant aggressive strategies for control. For example, foliar leaf spots are generally considered cosmetic diseases. Unlike blights or dieback diseases, which often have significant implications for plant health, most leaf spots are nothing more than unsightly.

It is strongly recommended that a plant health care plan be prepared for each property. The plan should include regular scouting to detect and identify diseases as early as possible. Scouting during peak periods should be done at least twice a month for trees and shrubs and, if possible, once a week for turf. In time, trends develop and “hot spots” of disease activity emerge. These hot spots are often consistent from year to year and are usually associated with microclimates in a landscape. Plotting these areas on a map is useful for future reference. It is also helpful to consult with fellow organic land care professionals and extension service, experiment station, and university personnel to keep informed about what others are seeing in the field and obtain results of disease forecasting or other prediction models.

Preferred

- Building and maintaining healthy, fertile soil (see Soil Health, page 9). Nutrient deficiencies and toxicities can weaken plants and make them more vulnerable to primary pathogens and also to secondary pathogens and/or opportunistic pests.
- Maintaining a soil pH that favors healthy growth (usually 6.4–7.0)
- Planting disease-resistant species and cultivars, when available

- Avoiding monocultures. If a disease takes hold, all of the plants in a stand are likely to suffer. A diverse landscape spreads risk and creates an ecosystem that can help keep pathogens under control.
- Carefully checking all nursery stock - roots as well as leaves and stems - for signs of disease before purchase
- Using adequate spacing to promote good air circulation and overall plant health
- Developing a plant health care plan to scout for diseases in the landscape
- Using the following sanitation practices. *Note:* Infected plant debris should be properly composted or removed from the site. If in doubt, infected material should not be composted.
 - o Pruning dead, dying, damaged, or diseased branches
 - o Removing infected leaves, twigs, branches, needles, and cones around the base of trees and shrubs in the fall to remove reservoirs of overwintering inoculum
 - o Removing infected grass clippings from the lawn
 - o Eliminating infected hosts and replanting with disease-resistant cultivars
 - o Crop rotation for annual plants
- Hydrogen peroxide
- Copper sulfate and fixed copper products - copper hydroxide, copper oxide, copper oxychloride. *Note:* Because copper accumulates in the soil, these products must be used sparingly. They must not be used as herbicides.
- Sulfur
- Lime sulfur
- Hydrated lime
- Neem products
- Narrow-range, or superior, horticultural spray oils derived from petroleum. These oils can be used during both the dormant and growing seasons.
- Peracetic acid, tetracycline (oxytetracycline calcium complex), and streptomycin - for use only to control fire blight in apples, pears, mountain ash, and other members of the rose family (*Rosaceae*)
- Ethanol, isopropanol (active ingredient in rubbing alcohol), hydrogen peroxide, and peracetic acid - used as disinfectants for pruning tools and other equipment. *Note:* Although the chlorine-containing materials calcium hypochlorite, chlorine dioxide, and sodium hypochlorite, at a concentration of 500 ppm (1 teaspoon of household bleach to 2 cups of water), are also allowed, they must be further diluted before disposal to below 5 ppm. This means diluting the 2 cups of bleach mix with an additional 12 gallons of water. In many cases this may be impractical.

Allowed

- EPA-registered beneficial microbes that antagonize or compete with specific pathogens
- Potassium bicarbonate
- Insecticidal soaps. *Note:* Insecticidal soaps can damage some plants. Apply with care.
- Plant-derived anti-desiccants and anti-transpirants
- Plant- or microbe-derived products formulated to enhance plant growth and improve soil health
- Plant-based oils, including those derived from garlic, neem, jojoba, cottonseed, and thyme
- Other plant extracts, such as saponins from *Chenopodium quinoa*

Prohibited

- All synthetic chemical fungicides other than those listed above
- Petrochemical-based anti-desiccants

WILDLIFE MANAGEMENT

Native animals of all kinds are essential to a healthy ecosystem. Priority must be given to protecting, maintaining, and improving critical habitats for wildlife, with the goals of increasing biodiversity and the stability of local ecosystems. In addition, humans often like to have some wildlife around purely for its aesthetic value. We must recognize, however, that wildlife can come into conflict with human beings in various ways: by injuring valued plants or crops, increasing the exposure of humans to pathogens (e.g., tick-borne diseases), or coming too close to humans (e.g., bears searching for bird seed). Some species may exceed not only the level of human tolerance (cultural carrying capacity) but also the capacity of the local environment to sustain their numbers (biological carrying capacity). Damage caused by wildlife may even be serious enough to degrade the ecosystem, causing erosion or pollution or a loss of biodiversity. Such conflicts between wildlife and humans may require diversion, the application of repellents, exclusion, or other management strategies. Management also requires the education of clients about wildlife behavior and actions that can be taken to reduce conflict, such as keeping compost covered and eliminating bird feeders.

Care must be taken to accurately identify the species that is causing damage (through identification of tracks, scat, behavior, and the type of damage) before determining a management strategy. It is wise to work with the client or community to identify an acceptable population threshold in the area before taking action to control the animals. State and local laws pertaining to live trapping, hunting, and removal of animals must be observed at all times.

Principles

- Humans and wildlife are parts of the same interdependent web of life.
- We must protect, maintain, and improve critical habitats for wildlife.
- Where management of wildlife is needed, we should make all possible efforts to respect the animals, minimize suffering, and educate the local human community.

Preferred

- Identifying landscape features that are important to biodiversity and wildlife and protecting or enhancing those features, particularly with respect to endangered and wetland species
- Improving or maintaining habitats identified as important for wildlife conservation in the local region. Check your State's Wildlife Action Plan at www.wildlifeactionplans.org for this information.
- Using plants that are avoided by wildlife, particularly deer. Native plants are recommended.
- Modifying habitat to prevent nesting or feeding by wildlife in areas used by humans
- Tree wraps (made of materials that are not prohibited in the Standards) to prevent girdling and other wildlife damage
- Fencing in selected areas, leaving corridors for wildlife to move safely
- Repellents based on plant materials or soap
- Human hair placed around the perimeter of an area containing plants favored by wildlife
- Mechanical or visual scaring devices
- Diversion plantings (planting favored plants in wildlife corridors to draw animals away from human landscapes)
- Barrier hedgerows composed of non-invasive species
- Netting
- Locating plants favored by wildlife in areas where humans are highly active and visible
- Educating the client in methods of preventing conflicts with wildlife (e.g., don't leave food on the ground, don't feed the dog outside, cover the compost pile if it contains kitchen scraps, remove bird feeders, keep domestic cats indoors)

Allowed

- Repellents based on ammonium salts of fatty acids, such as Hinder® deer repellent
- Capsaicin-based animal repellents, such as Miller's Hot Sauce® animal repellent
- Dried blood or animal renderings used as a repellent. Caution: These materials must come only from American cattle to avoid the risk of infectious diseases. Take precautions to avoid direct human contact. These materials may contain pathogens.
- Trapping in accordance with state laws and best management practices published by the Association of Fish & Wildlife Agencies (www.fishwildlife.org)
- Hunting in accordance with state laws
- Rodenticides with Vitamin D3 as the active ingredient
- Dogs used in a fenced, confined area or under direct supervision (as when trained dogs are used, under supervision, to discourage Canada geese)
- Carbon monoxide or sulfur dioxide smoke bombs, when used for underground rodent control

Prohibited

- Any products prohibited by state laws
- Traps that cause slow death or injury (those that violate the best management practices published by the Association of Fish and Wildlife Agencies, www.fishwildlife.org)
- Rodenticides with an active ingredient other than Vitamin D3
- Predator urine. Prohibited due to inhumane conditions of urine collection.
- Diesel fuel and kerosene-based sprays
- Cyanides, strychnine, phosgene bombs, and other gas-producing devices
- Products containing sewage sludge, such as Milorganite®

DISPOSAL GUIDELINES FOR PLANT RESIDUES AND OTHER LANDSCAPING MATERIALS

Organic land care professionals should comply with local town or city regulations regarding the disposal of any nondegradable materials such as pressure-treated lumber, concrete, asphalt, and other building debris. Dumpster rental may be required. Disposal of degradable materials, such as stumps, logs, and brush may also be regulated locally or by state statute. Invasive plant parts must be disposed of appropriately to prevent spread (see Native, Exotic, and Invasive Plants, page 37).

Preferred

- On-site composting of degradable materials
- Grinding stumps and brush to chips for reuse on site

Allowed

- Composting off site
- Removing stumps and brush to an off-site composting facility
- Other disposal methods, such as burning, as permitted under local ordinances and state laws

Prohibited

- Dumping off site in unauthorized areas
- Disposal of invasive plant material in ways that could lead to the spread of such plants

APPENDIX I: SOURCES OF MORE INFORMATION

Baystate Organic Certifiers

USDA National Organic Program accredited certifying agent. Maintains the NOFA Organic Land Care approved materials list for organic landscaping.
1220 Cedarwood Circle, N. Dighton, MA 02764
774-872-5544; www.baystateorganic.org

Bio-Integral Resource Center (BIRC)

Non-toxic and least toxic integrated pest management solutions to urban and agricultural pest problems.
Publications include: *The IPM Practitioner* and *Common Sense Pest Control Quarterly*.
BIRC, P.O. Box 7414, Berkeley, CA 94707
510-524-2567; www.birc.org

Connecticut Agricultural Experiment Station

Publications, soil testing, identification of pests and plant diseases.
CAES, P.O. Box 1106, 123 Huntington St.
New Haven, CT 06504.

APPENDIX III: SOIL TESTING LABS

Here is a partial listing of soil testing labs in the Northeast. The National Sustainable Agriculture Information Service also maintains a list of "Alternative Soil Testing Laboratories" across the country. Contact ATTRA at P.O. Box 3657, Fayetteville AR 72702, 800 346-9140, or online at www.attra.org/attra-pub/soil-lab.html.

Commercial Labs

Agri Analysis, Inc.

280 Newport Road
Leola, PA 17546
1-800-464-6019
